SUPREME COURT

No. 2023AP001399-OA

IN THE SUPREME COURT OF WISCONSIN

REBECCA CLARKE, RUBEN ANTHONY, TERRY DAWSON, DANA GLASSTEIN, ANN GROVES-LLOYD, CARL HUJET, JERRY IVERSON, TIA JOHNSON, ANGIE KIRST, SELIKA LAWTON, FABIAN MALDONADO, ANNEMARIE MCCLELLAN, JAMES MCNETT, BRITTANY MURIELLO, ELA JOOSTEN (PARI) SCHILS, NATHANIEL SLACK, MARY SMITH-JOHNSON, DENISE (DEE) SWEET, AND GABRIELLE YOUNG,

Petitioners,

GOVERNOR TONY EVERS, IN HIS OFFICIAL CAPACITY; NATHAN ATKINSON, STEPHEN JOSEPH WRIGHT, GARY KRENZ, SARAH J. HAMILTON, JEAN-LUC THIFFEAULT, SOMESH JHA, JOANNE KANE, AND LEAH DUDLEY,

Intervenors-Petitioners,

v.

WISCONSIN ELECTIONS COMMISSION; DON MILLIS, ROBERT F. SPINDELL, JR., MARK L. THOMSEN, ANN S. JACOBS, MARGE BOSTELMANN, AND JOSEPH J. CZARNEZKI, IN THEIR OFFICIAL CAPACITIES AS MEMBERS OF THE WISCONSIN ELECTIONS COMMISSION; MEAGAN WOLFE, IN HER OFFICIAL CAPACITY AS THE ADMINISTRATOR OF THE WISCONSIN ELECTIONS COMMISSION; SENATOR ANDRÉ JACQUE, SENATOR TIM CARPENTER, SENATOR ROB HUTTON, SENATOR CHRIS LARSON, SENATOR DEVIN LEMAHIEU, SENATOR STEPHEN L. NASS, SENATOR JOHN JAGLER, SENATOR MARK SPREITZER, SENATOR HOWARD L. MARKLEIN, SENATOR RACHAEL CABRAL-GUEVARA, SENATOR VAN H. WANGGAARD, SENATOR JESSE L. JAMES, SENATOR ROMAINE ROBERT QUINN, SENATOR DIANNE H. HESSELBEIN, SENATOR CORY TOMCZYK, SENATOR JEFF SMITH, AND SENATOR CHRIS KAPENGA, IN THEIR OFFICIAL CAPACITIES AS MEMBERS OF THE WISCONSIN SENATE,

Respondents,

WISCONSIN LEGISLATURE; BILLIE JOHNSON, CHRIS GOEBEL, ED PERKINS, ERIC O'KEEFE, JOE SANFELIPPO, TERRY MOULTON, ROBERT JENSEN, RON ZAHN, RUTH ELMER, AND RUTH STRECK,

Intervenors-Respondents.

Export Report of Brian J. Gaines: Citizen Partisanship and Partisan Neutrality

January 19, 2024

Author: I am Brian J. Gaines, a Professor of Political Science at the University of Illinois Urbana-Champaign and the Honorable W. Russell Arrington Professor in State Politics for the University of Illinois system. I hold a BA (with honours) from the University of British Columbia (1988), and AM (1989) and PhD (1995) degrees from Stanford University. Most of my research deals with elections, electoral behavior, and electoral institutions, and I have published articles in numerous academic journals, including *The American Journal of Political Science*, *The American Statistician*, *The Journal of Politics*, *Political Analysis*, and *Political Behavior*. I am a past editor (2011-15) of *American Politics Research* and past co-editor (2010-13, with Wendy Cho and Jake Bowers) of the *The Political Methodologist*. I was on the staff of the Royal Commission for Electoral Boundaries that redrew the districts for the provincial legislature of British Columbia (the "Fisher Commission") in 1987 and 1988. I have offered expert testimony and/or supporting analysis in cases dealing with various aspects of election administration, including *Susan C. Hileman v. Sharon McGinness and Louis Maze* (Circuit Court of Alexander County, No. 2000-MR-24), *Whitford v. Gill*, Case o. 15-cv-421-jdp, 2018-19, *American Women v. Missouri*, 2020 (election administration), Circuit Ct. 20 AC-CC00333, and *Johnson v. Wisconsin Elections Commission*, 2021-22. I was compensated for preparing this report, at \$450 per hour. My compensation was in no way contingent on the opinions offered or the outcome of the case. The views expressed below are my own and not those of the University of Illinois.

Executive Summary

Counsel for the Wisconsin State Legislature asked me to opine on aspects of partisanship of individual Americans, how affect for parties relates to voting, and how partisanship aggregates from individuals to electorates, as formed by district electoral boundaries, with attention to possible standards for "partisan neutrality." Below, I advance the following points.

- Generally, understanding partisanship as a dichotomy, wherein Americans are either Democrats or Republicans, is a common, sometimes useful simplification, but also a significant distortion of how Americans relate to the major parties. Many are neither and some are, in degree, both.

- American ballots nearly always feature multiple partisan offices. Many voters support candidates from different parties on a single ballot. Assuming that Americans are all *strict* partisans, implicitly or explicitly, ignores countervailing evidence.
- Electorates, as aggregations of individuals, also have partisanship, but it can be less stable and predictable than the individual-level counterpart, because of variance across individuals in degree of attachment to parties and changes in composition of the electorates.
- The standard of neutrality, or fairness, to parties, when applied to parties in the electorate rather than to formal organizations or elected partisan officials, is more elastic and ambiguous, given the complexities of aggregating the fuzzier associations that apply to ordinary voters and major parties.
- Partisan neutrality in plurality-rule elections should not be construed to mean perfect or nearly perfect proportionality between vote shares and seat shares.
- Estimation of how a given electoral system—including, but not strictly limited to the electoral boundaries—translates votes into seats for each party is a difficult task, subject to much uncertainty and ambiguity, particularly when done prospectively.
- There is some public support for approximate seat-vote proportionality in election outcomes, but it is not clearly prioritized more highly than other, potentially competing criteria, including that maps should closely follow existing boundaries such as county and city lines to the extent possible.

1 The Nature of Partisanship

Modern American politics revolves around competition between two major parties, Republicans and Democrats. Individual Americans vary in their attitudes, attractions, and antipathies towards these parties. Some self-identify with one major party, and others do not. In popular jargon, the latter are termed “independents.” Whether independent Americans, who see themselves as neither Republicans nor Democrats, constitute about one-third or only about one-tenth of the adult population is unclear, and depends on how one asks and interprets survey questions gauging partisanship.

The precise wording of survey items (that, is questions and options) varies, but a very popular approach, as developed by the American National Election Study series starting in 1952, is a series of nested questions, beginning with, “Generally speaking, do you usually think of yourself as a Republican, a Democrat, an independent, or what?”¹ Those answering “Republican” or “Democrat” are asked, as a follow-up, “Would you call yourself a strong (Republican/Democrat) or a not very strong (Republican/Democrat)?” Those who declare themselves independent, and sometimes those who name a different party, are asked, “Do you think of yourself as closer to the Republican or Democratic party?” This question design provides two alternative estimates of the proportions that are Republican, Democratic, and neither, or independent. The first question

¹The ordering of options is sometimes randomized or rotated, so that not all respondents get precisely the same wording. Capitalization of “independent” is not uncommon, but is misleading, as there is no formal party of that name to justify elevation to proper-noun status.

creates a three-way classification scheme. Combined, the questions create a seven-category classification, assumed to be ordered: strong Republican, not-strong Republican, independent closer to the Republican party, independent not closer to either party, independent closer to the Democratic Party, not-strong Democrat, strong Democrat. (Those respondents who decline to answer the first question, sometimes by disavowing any interest in politics, are usually ignored in analysis. Sometimes, those who respond to the "...or what?" cue are likewise set aside. Some respondents will answer the first question, but decline to answer the follow-up. Usually there are fairly few such respondents, but not none at all, and, again, they are mainly ignored in analysis.) The nickname "leaners" is often assigned to those who initially profess independence, but then acknowledge being closer to a major party, even though the questions make no mention of "leaning." Sometimes the strength follow-up is omitted, so that the larger classification scheme has only 5 categories. There are strong assumptions underlying this variable construction, that one cannot be both Republican and Democrat, in degrees, and that positive affect for one party equates with negative affect for the other. In countries with multi-party systems, those assumptions are far less natural. Indeed, in many other democracies, the whole notion that residents "identify" with parties is open to debate. Outside the United States, many scholars conceive of citizen-party interactions chiefly as a matter of voting behavior, and not deep-seated identity (e.g., Paparo, De Sio, and Brady 2020).

In a November 2023 Marquette Law School Poll of Wisconsin registered voters, for instance, when asked the first question, 34 percent chose Republican, 35 percent Democrat, 24 percent independent, and 8 percent volunteered some other answer, or declined to answer. Once the independents and others were asked, "Do you think of yourself as closer to the Republican Party or to the Democratic Party?", with no explicit options of "neither" or "both" offered, most relented and chose. They were almost equally divided, leading to a quite different portrait: 46 percent Democrat or Democratic leaner, 45 percent Republican or Republican leaner, 10 percent independent or other.²

The example is merely illustrative, but very typical. A sizable share of survey respondents who deny partisanship when asked only once can be nudged or cajoled into declaring a preference on a second query. In a lively debate over whether these leaning (or "closet" or "shy") partisans should be regarded as true partisans, most of the evidence in the affirmative consists of demonstrations that their other survey responses pertaining to parties, including vote reports, more closely resemble those of self-described partisans than those of twice-self-described independents (e.g. Keith et al. 1992, Magleby et al. 2011). Fiorina (2018) offers one rebuttal, based on panel data (repeat interviews with the same individuals). The partisan leaning expressed at the second prompt might reflect a short-term vote intention, rather than an ambivalent or reluctantly revealed deeper attachment. This distinction is important because at least since the publication of the highly influential *The American Voter* in 1960, most American political scientists have conceived of partisan identification as a long-term, slow-changing trait of potential voters, predictive of voting behavior, but not identical, and causally prior. So while political scientists will sometimes infer partisanship from voting behavior, the two are not regarded as identical, whether considering an individual ("micro-partisanship") or of a collection of individuals ("macro-partisanship"). The question of whether a small majority or a very large majority of Americans are partisans is, in part, bound up with the distinct question of how separate are attachments to parties and near-term voting plans or very recent vote history. Generally, a case can be made for two different answers to the question, "How many eligible voters are not partisan?" Whether one answers "30-40 percent" or "about 10 percent", a further qualification is "...with variation from place to place and from election to elec-

²Marquette Law School Poll, November 2-7, 2023.

tion." No one seriously proposes explicitly that all American eligible voters or even actual voters are partisans, even though that assumption lurks behind much work, and the equation of select votes with partisan identity is quite common.

There is, in turn, a large, ongoing academic debate on whether partisanship should be seen as an identity (akin to a religion, mother tongue, sexual orientation, nationality, or maybe even long-standing sports-team allegiance) or, instead, a short-term, comparative preference (as in, "right now, I would prefer pasta to beef" or "I've been running less and swimming more lately"). Those who devised the survey items discussed above generally took the former view. Revisionists later emphasized that data strongly adjudicating between these rival understandings are hard to come by. Some studies pushing the "identity" view emphasize novel findings on how partisan judgment sometimes shows up in non-political contexts, as when people report liking their neighborhood less when told that their neighbors are less like them in partisanship than they thought (Hui 2013), or express opposition to having their children marry someone from the other party (Iyengar et al. 2012). However, such findings often amount to demonstrating "some effect" rather than a perfect sorting, and they are also sometimes contradicted. For instance, other studies suggest that the importance people say they attach to "similar political views" in how they evaluate a possible spouse was negligible in 1939 and equally so in 2008 (Fiorina 2018, 61)). Despite many innovative studies exploring the breadth and depth of partisan attachments in recent decades, the quiddity of partisanship remains debated. It is plainly not a nearly immutable trait on par with race or sex, let alone age. There is no consensus that it is genuinely as strong or enduring as religious identification, although with both religion and party, the "none"s are an important category not to be overlooked. Insofar as there is evidence that the significance of partisanship for political actions has varied over time, there is little consensus on precisely why it waxes and wanes, and there is no reason to think that a period of increasingly intense partisan separation or polarization is ever irreversible. So, the argument that "this is an era of stronger partisanship" should not be confused with "...of perfect partisan sorting" and one should certainly not infer that present-day patterns will necessarily persist forever.

2 Parties and Partisans

Neutrality in regard to parties is not strictly identical to neutrality between individuals, some of whom have partisan persuasions. There are doubtless abundant important legal principles and distinctions regarding rights, as enjoyed by institutions or organizations like parties, and those belonging to individuals who constitute those organizations. My point hereafter is not to rehearse legal points, but to emphasize that a dichotomy in the party system need not be indicative of that exact same dichotomy within the electorate. An electorate that tends to split its vote about 55% for A and about 45% for B over a period of time will almost never consist of 55 % died-in-wool supporters of party A and 45 % rock-ribbed supporters of party B. There will be variations across distinct electoral contests, and probably even larger potential variations across unobserved, hypothetical contests. In that sense, the average or normal vote (Converse 1967) observed from a set of contests (over a small set of election years) can be highly conditional on such factors as kinds of competition taking place, turnout patterns, issues at play, demographic traits or geographic bases of candidates, spending levels, and even ballot and voting procedures. The same voters confronted by a different set of candidates, with slightly different electoral institutions, might have exhibited different patterns of partisanship. Voter behavior is indicative of partisanship, but

not only of partisanship, which is harder to measure and more amorphous.

Split-ticket voting, simultaneously supporting candidates from different parties in races for different offices, offers one glimpse of internal variance in partisanship as a categorical variable for individual voters. There are certainly some voters who pay scant attention to candidates, beyond which party they represent, and will back all Democrats or all Republicans. Other voters, attentive to candidate traits, will usually refrain from supporting candidates from one party, but will also decline to support *all* of the candidates from their preferred party. And other voters, perhaps even more attuned to aspects of candidates other than party, such as sex, likeability, record of helping constituents, etc., will, on a single ballot, support candidates from both major parties.

A quick comparison of outcomes from races that appeared on the same ballot confirms the point. Consider the 2022 contests for Governor and Lieutenant Governor and for U.S. Senator in Wisconsin. The Democratic pair of Tony Evers and Sara Rodriguez triumphed in the gubernatorial race, with about 51.2% of the vote. Meanwhile, the Democratic Senate candidate, Lieutenant Governor Mandela Barnes, took about 49.4% of the vote, narrowly losing to incumbent Republican Senator Ron Johnson. From the aggregate vote totals, one can tell that thousands of voters backed only one of the Democrats or only one of the Republicans. Usually, logical bounds on exactly how many ballots of each type could have gone into those vote totals are very uninformative, leaving the true degree of splitting unknown, and not easily estimated. With ballot images, however, the exact numbers of each possible combination of votes are observed.

Dane is one of the few counties, in Wisconsin or elsewhere, that makes a data set of ballot images publicly available for a period of time after each major election. These data record exact descriptions of the mixture of votes on each ballot, and so provide the necessary information to know how much splitting, and what variety, took place. In Dane, Senator Johnson's vote total was nearly 6,000 votes higher than that of the GOP gubernatorial ticket, Tim Michels and Roger Roth, while the Evers/Rodriguez slate won nearly 5,000 votes more than did then Lieutenant Governor Barnes, in his senate bid. From the ballot-image data, one can compute that ballots with votes for Democrats in both races constituted about 75.5% of the total, while straight Republican ballots were another 19.9%. Roughly 1% of the ballots had exactly one Democratic vote and no Republican votes. Around 0.5% were the mirror image, having one Republican vote and no Democratic votes. About 2.2% of the ballots had votes for both winners, Democrats Evers/Rodriguez in the gubernatorial column and Republican Johnson in the Senate race. Another 0.5% were ballots with votes cast for both losers, the Republicans Michels and Roth and the Democrat Barnes. Finally, about 0.2% of the ballots featured no votes for either major party, as they combined support for an independent gubernatorial slate, write-in votes, or abstentions.

Figure 1 shows a breakdown of ballots cast in Dane County in the 2022 election taking into account all of the partisan races. These data provide a finer, more detailed sense of voters' partisan loyalties than aggregate data, which are inherently ambiguous, or surveys, which generally do not cover the full panoply of offices on long American ballots, and also exhibit sampling and measurement error (Weisberg 2005). In 2022, voters in Dane County had the option to participate in as many as 10 statewide, county-wide or districted contests. A few races were uncontested by one major party, so depending on precinct, voters could cast 8, 9, or 10 Democratic votes and 7, 8, or 9 Republican votes, or could, instead, abstain, support a minor-party candidate, or write in an alternative choice.³

³There were five statewide contests, for U.S. Senator, the Governor-Lieutenant Governor slate, Attorney General, Treasurer, and Secretary of State. The two county-wide offices up were sheriff and clerk of the county court, the latter race featuring no Republican candidate. There were up to three districted contests. All of the voters in the county were in the

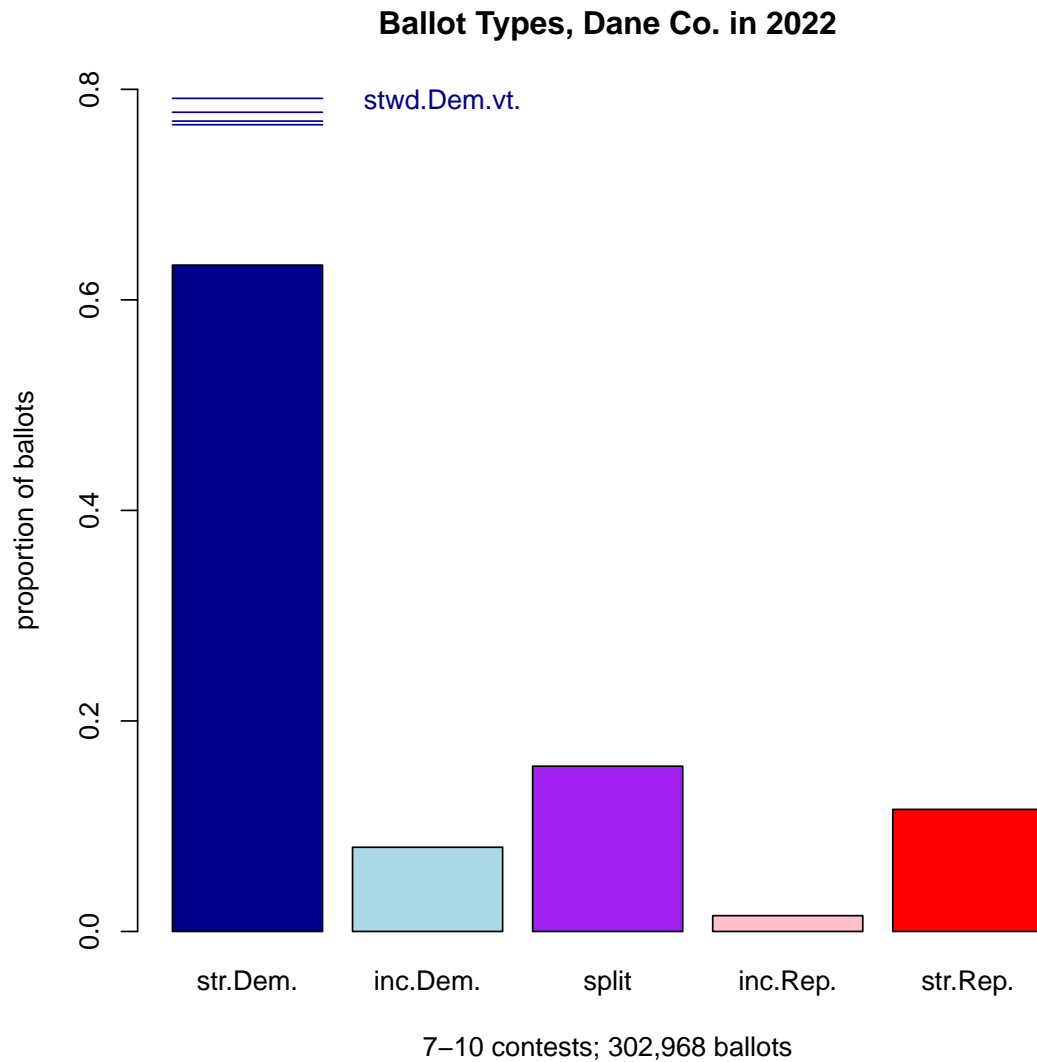

The figure classifies ballots according to whether or not they exhibit divided or limited partisan loyalties as follows. Voters who cast the maximum number of possible ballots (between 7 and 10, depending on location) for one party and none at all for the other major party are deemed “straight(-ticket)” partisans. The dark blue and dark red bars show what proportion of all 2022 Dane voters were straight Democrats (about 63%) or straight Republicans (about 12%), respectively. Voters who supported only candidates from one major party, but did not support all of them, are coded as “incomplete” partisans. The light blue bar shows that about 8% of the voters backed some Democrats, and no Republicans, without supporting all of the Democrats. The pink bars show that about 2% of the voters were, analogously, incomplete Republicans. Voters who supported at least one candidate from each party, and the very few who supported no Republicans or Democrats at all, are in the “split” category. The purple bar shows that they constituted about 16% of the voters, or roughly 50,000 individuals in this one county.

Dane County, home to the second largest city in the state, Madison, is a heavily Democratic jurisdiction, so it is little surprise that the dark blue bars towers over the others. But when one focuses on the normal vote of an electorate residing in a geographic entity, there is some tendency to under-appreciate the diversity of its composition. The dark blue lines above the straight-Democrat bar show the two-party vote share for the Democratic candidates in the contested statewide races, for U.S. Senator, Governor/Lieutenant Governor, Attorney General, Secretary of State, and Treasurer, all just under 80%. It is common to average vote totals of those sorts into an estimated normal vote, which is then taken to characterize the party leanings of the electorate, in a county, district, or smaller geographic region. This figure is a reminder that Democratic (and Republican) candidates accrue votes not only from utterly loyal Democrats (or Republicans), but from a substantial number of voters with mixed preferences, reservations about some of the candidates fielded by their preferred party, admiration for other-party candidates, or, in many cases, little or no sense of actually having a party of their own.

There is little reason to suspect that Dane sees unusually high splitting. Given its dramatic partisan skew, the converse is perhaps more likely. The gaps between aggregate votes determine maximum levels of straight voting, and in the contests for US Senator and Governor/Lieutenant Governor, broached above, Dane was on the low end for Wisconsin’s counties. Its alphabetical neighbor Crawford County, for instance, saw more than twice as large a gap, with the Evers-Rodriguez ticket having outpolled Barnes by about 3.5 percentage points, versus roughly 1.5 points in Dane. A figure for one county in one year is merely illustrative, and opportunistic given the scarcity of ballot-image data sets. But the point is general: in a two-party system, normal voters do not come in only two types, however the normal vote is estimated.

second U.S. House district. Voters were in one of twelve distinct Assembly districts, three of which lacked a Republican candidate. Some voters were in one of three state Senate districts having a 2022 election, one of which lacked a Democratic candidate.

Figure 1: Straight- and Spit-Ticket Voting in Dane County, 2022

Voters who opt, on a single ballot, to support some candidates from different parties are obviously not assessing candidates only on the basis of party. And if it is something of a truism to note that politically engaged citizens become somewhat partisan in systems where competition is organized by parties, it is equally obvious that candidates can attract or repel votes in many, many ways beyond their party labels.

The point that contests most of which feature one Republican and one Democrat generate some degree of regularity in the two-party breakdown is notable, but there is also scope for misconstru-

ing those patterns as stronger, more stable attachments of the actual citizens doing the voting than is, in fact, lurking beneath.

3 From Votes to Seats

Political scientists often simplify the very large array of possible electoral rules into a simple dichotomy between proportional and plurality systems (e.g., Lijphart 2012). The former assign seats to parties in proportion to their vote shares, with various constraints, exceptions, and qualifications, so that seat shares are, by design, approximately proportional to vote shares. One common example of a constraint, that curtails exact proportionality, is that parties are often awarded seats only if their vote share surpasses some minimal threshold. Proportional assignment can be done for an entire polity, as is done for the parliament of Israel and the lower house in the parliament of the Netherlands, but more often it takes place in each of a number of multi-member districts. In the aggregation from district to national totals, some proportionality can be lost. Moreover, it transpires that there are many ways to do the necessary rounding to convert shares into integers, given a fixed number of seats (Balinksi and Young 1982). In turn, there are many different form of “proportional representation” (for short, “PR”) electoral rules. Generally, however, PR produces roughly proportional vote and seat shares for at least a subset of parties.

In plurality systems, by contrast, seats are awarded individually, to whichever candidate(s) win(s) the most votes in a district, with no attention to other districts’ results. In turn, there is no automatic relationship between votes and seats. For example, it is logically possible, though empirically vanishingly rare, for parties that almost exactly tie in votes to win 0 percent and 100 percent of the seats, respectively, even without differences in district vote totals. If each of 100 single-member districts saw a result of 10,001 for the candidate of party A and 9,999 for the candidate of party B, the resulting vote shares would be 50.005 % to A and 49.995 % to B, and the seat shares would be 0 % and 100 % to A and B. Generally, proportionality is not built into the system under most-votes-wins rules, and if it arises, it arises in some degree by accident.

There are many other ways to structure voting, beyond nation-wide PR and single-member-district plurality. Just the same, comparative political science quite often forces more complicated systems, involving cumulative or transferable votes, majority requirements, or blends of distinct rules in “mixed systems”, into one or other category for simplicity in comparative analysis. For present purposes, the critical point is that some electoral systems are essentially designed to be highly proportional in vote shares and seat shares, and others are not. Single-member plurality competition, the most common electoral system in the US, is not a proportional method by design.

It follows that judging a map by whether the more successful party won a larger seat share than vote share is not an apt or sensible gauge of the fairness of the system when plurality rule obtains. A *very* large discrepancy in these shares can be a useful, crude diagnostic, in a qualitative sense, but there is not a common standard for how big a gap is too big to be reasonable, and mere comparison of shares ignores the myriad possible sources of disproportionality. The huge 50 % gap in the contrived, stylized example above is, in fact, not indicative of an unfair map, given that every race was essentially a tie, with party A candidates having won each seat by good fortune.⁴

⁴Getting 100 heads in 100 tosses of a fair coin is nearly, but not literally, impossible. The single most likely outcome of exactly 50 heads, meanwhile, is expected to happen less than ten percent of the time. An expectation of (rough) propor-

One answer to how a set of electoral districts in a plurality system can exhibit partisan neutrality begins, just the same, with the mathematical relationship between aggregate vote shares and seat shares for the parties, often called the vote-seat (or seat-vote) “curve” or “function.” Fairness, on this logic, is not exact proportionality, but, rather, symmetry, such that the parties reap about the same share of seats from any given vote share. If both parties A and B can win about 60% of the seats with a 55% vote share, for example, the system could, on this logic, be judged as fair in that vote range. It would equally be fair or unbiased if they each won 65% of the seats from 55% of the votes, and it would also thereby be more sensitive or “responsive” to vote gaps. An implication is that exact 50-50 vote ties should result in something close to 50-50 seat ties, although what “close” means is not obvious, and symmetry is not exclusively about the seats shares (expected or observed) when vote shares are nearly identical. Because symmetry can be assessed at different vote shares, it is necessarily complicated.

An immediate difficulty in applying such logic is that there is never any guarantee that one will observe, in a few relatively proximate elections, different parties winning nearly the same vote share. And without an unrealistically large number of elections, the performance of the system will only ever be observed over a few possible vote shares. So, a typical method of making such comparisons, to evaluate symmetry, involves simulating unobserved outcomes. The project of representing the translation of vote-share vectors into seat-share vectors for a set of elections with a mathematical function is very old, dating from Edgeworth’s pioneering work (1898). Writing down a theoretical function or a statistical model for an empirical function is easier when there are only two parties, not more than two. However, under plurality rule, estimation involves a number of tricky issues, even when done after-the-fact, from a set of observed election results (i.e. vote shares and seat shares for the parties) in a system dominated by two parties. Some of the key challenges include: (a) races uncontested by one major party will tend to make aggregate vote share noisy or distorted; (b) how to cope with some minor-party or independent candidates who garner non-trivial vote shares is not obvious; (c) when elections are staggered, so that not all seats are up at each election, interpretation of aggregates is necessarily conditional and more complicated; (d) turnout normally varies across districts so that aggregate vote shares differ from (unweighted) average vote shares, and some of the complications associated with more than two vote shares arise when the non-voter share is included; (e) over the lifetime of a 10-year electoral map, district populations diverge, so that even apart from different typical turnouts, districts can vary substantially in their contribution to the vote aggregate, but not to the seat aggregate; (f) whether vote shares are adjusted or modeled for such factors as incumbency advantage, party “tides,” candidate quality, spending levels, and so on, can be quite consequential, but there is nothing like consensus on which variables should be employed, if any, to generate “normal” vote shares.

All of the points above can be addressed with some assumptions. My claim is not that it is impossible to do analysis, but, rather, that the challenges are many, and that many different approaches, generating different findings, can all seem reasonable. For instance, many analyses tackle uncontested races by imputing for each contest lacking a Democrat or Republican a hypothetical district result for the unobserved contested race. This imputation can be done using prior elections or contests for other offices in the given district and same election, or both. In the simplest move, one swaps vote for presidential candidates or gubernatorial candidates for votes in the leg-

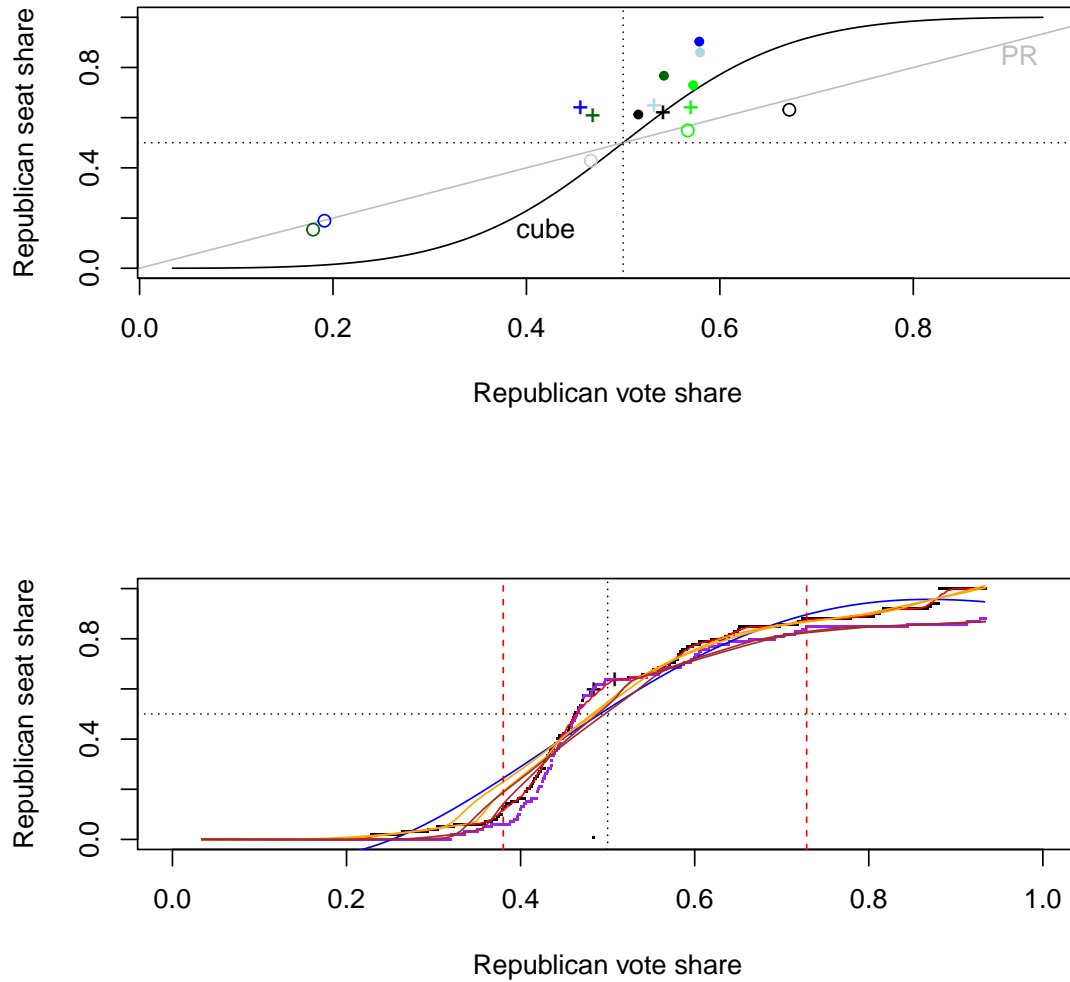

tionality is different from a realization thereof, and the uncertainty about the expected value is important. “We expect (but never guarantee) that about 94% of the time we will see between 41 and 59 heads” is a far more informative description than “we expect 50 heads,” as the latter ignores large uncertainty.

islative races of interest, as though they are equivalent. Of course, they are not, and demonstration of high correlation does not necessarily establish that they are somehow “close enough.” There are many ways to try to solve the missing-data problem caused by absence of candidates, but all attempted solutions carry uncertainty associated with estimation of unknowns. That uncertainty will multiply in later stages of analysis. Very often, analysts simply ignore all such uncertainty, for simplicity. This is a point that will recur in brief discussion of some analysis in some other expert reports, below.

Beyond those uncertainties, any retrospective assessment of how a given electoral map translated votes into seats is inherently difficult because of limited data. In a typical American case, one observes at most five elections over a decennial apportionment period, with even fewer data points if there are any boundary alterations beyond the post-Census redistricting. Each election is essentially one observation of the vote-share, seat-share pair, and five is a very small number of data points for estimating even a simple linear function, let alone a more complicated function of the sort typically postulated to fit plurality elections. A common strategy for getting around the paucity of data is to generate a large number of hypothetical election results, from each observed data point or from some variety of average across the five observed cases. One such method is to assume a “uniform swing” and map out what seat shares would have obtained had a party gained (lost) exactly the same percentage points of vote in each district. There are, of course, many, many other ways to posit vote swings that produce unobserved, counter-factual or simulated vote-seat data points from a lone observed point. Any such model of swings rests on assumptions, that perhaps can be assessed as more or less plausible by comparisons of some kind, but cannot be verified as correct, as such, given that they are inherently counter-factual.

It is worth reiterating that a seat-vote analysis assesses not strictly the map, but an electoral system. With single-member districts and plurality rule, the electoral boundaries are extremely important, of course, but a host of other rules, governing ballot access for parties, ballot format, and election administration, broadly, are also important to outcomes.

Figure 2: Wisconsin Assembly Seat-Vote Functions

The top panel of Figure 2 shows, with crosses, the aggregate Republican vote and seat shares for the 2012-2020 elections. (Colors identify elections, with dark green for 2012, light green for 2014, light blue for 2016, dark blue for 2018 and black for 2020). The vote shares include the many races uncontested by one major party. At a glance, one sees much more variance in vote shares than in seat shares. How important are those races without competition? The solid and hollow circles separate races according to whether or not candidates from both major parties contested the seat. For instance, in 2012, 22 Democrats were elected without facing any Republican opponent,

while only 4 Republicans won seats without any Democratic opponent. Adding up the major-party votes across those 26 uncontested races, Republicans won about 18% of the vote, and won $\frac{4}{26} \approx 15\%$ of the seats. It happens that the uncontested vote and seat shares, marked with hollow circles, fall nearly on the diagonal, exact-proportionality line (marked “PR”) in this period. The black curve shows the “cube rule,” a theoretical prediction popularized by Kendall and Stuart’s influential analysis of early Twentieth Century data from the UK and select US elections (1950), that predicts seats ratios equal to the third power of vote ratios. In this panel, the solid circles show shares for contested races, and some of these fall fairly close to the cube-rule function. It seems clear that what conclusion one draws about partisan symmetry or bias could depend on how the ambiguity of uncontested races is resolved.

The bottom panel shows a few possible seat-vote curves fitted to these data by the following steps. First, a model of district “normal vote” was estimated, using only the contested races. The model employed only one additional predictor variable, an indicator for whether each contest featured a Republican or Democratic incumbent, signed so that it estimated an identically sized vote-share advantage, using only full-term incumbents (and not special-election winners). The model was then:

$$V_{it} = \eta_i + \alpha_t + \beta I_{it} + \epsilon$$

where η_i are indicators for each district (district “fixed effects”), the α terms are election-year indicators (time fixed effects), V is the Republican two-party vote share in district i and election t , and I_{it} is an indicator of an incumbent running in district i , election t , positive for Republican incumbents and negative for Democratic incumbents. The ϵ term represents error or noise. The estimated incumbency advantage, $\hat{\beta}$ was about 2.5 percentage points. Those effects are effectively removed from the observed vote totals, so that the vote-seat mapping is intended to be free of a distinct incumbency effect. Six districts were never contested over those five cycles, with districts 10, 16, 18, 77, 78 never having seen a Republican and 59 never having hosted a Democratic candidate. For these districts, absent from model estimation, I imputed the appropriate least competitive district whose normal vote could be estimated from at least one contested race. The normal votes were weighted by average turnout in two ways. One version used 2012, before populations had drifted very much, and the second employed the whole period. Products of normal vote share for each district and vote-total weights produce an average Republican vote share for the map over the decade. The two crosses in the vicinity of (.5, .6) show those two estimated data points.

Two sets of small data points mark out the results of distinct uniform-swing simulations. To observe symmetry or asymmetry in the treatment of parties, one requires not the single data point reflecting average results, but a set of hypothetical outcomes. As the Republican vote share falls or rises from this decade average (the one based on the 2012 weights was used), assuming the same relative strength for the party across the districts, the seat share adjusts accordingly. A uniform percentage-point swing ceases to work (respect bounds) when any district bottoms out at 0 or tops off at 100 percent of the vote, without further adjustment. Thereafter, the swing can be conditionally uniform, for districts that have votes remaining to lose or gain. The vertical dashed lines mark the range of the uniform swing for this simulation, which can be viewed as the portion for which seat-share estimates are more internally consistent. The second set of hypothetical data points, in purple, allocates a shifting total Republican vote to each district to maintain each district’s relative share of the total, and so does not face this zeroing-out challenge.

The red line fit over the first points is an extremely local locally weighted regression. Blue, brown, and orange lines are much smoother trend lines, fit to the same data, but with parameters chosen to produce much simpler shapes, treating more of the simulated variance in the data points

as noise. Rather than compute uncertainty intervals for predictions, I merely note the large variation across distinct predictions, all of which are estimates steeped in assumptions and uncertainty.

None of these estimates is meant to be in any way definitive. The point of the exercise is not to provide a single best answer to whether the 2012-20 Wisconsin Assembly map was or was not partisan neutral, nor to generate a score for its neutrality on some low-to-high scale. Rather, I wish primarily to emphasize that even after observing five elections, estimation of statistical parameters to capture bias or responsiveness of the map always entails many assumptions and much uncertainty. There is no shortage of statistical models for converting election data into estimates of relevant parameters (e.g., Gelman and King 1990, 1994) But there is not a consensus on the correct or best approach, and every approach both invokes strong assumptions and necessarily involves multiple sources of uncertainty, arising from statistical estimation and combination and comparison of statistically estimated quantities. Other analysts might estimate normal vote with a different, more complicated model including such measures as challenger quality, spending ratios, female-candidate effects, etc. There are countless ways to create hypothetical outcomes with swings, for instance so that they are proportional to observed inter-election swings rather than uniform. The best model for trend in those hypothetical data points is wide open to debate. And on, and on.

It might be appealing to equate partisan symmetry with a symmetrical vote-seat function, but the assessment of symmetry from complicated estimation is inherently fraught. The example above was based on retrospective analysis of observed returns, but assessing a map before elections have been held brings in yet another stage with inherent difficulty, projecting future results from past results. This is, again, a common task for psephologists, but also one that inherently involves assumptions and the possibility of error.

One “solution” to the myriad challenge of modelling is to assume away the need to model. The “efficiency gap,” a somewhat popular measure of partisan fairness in recent years, is perhaps the prime example (Stephanopolous and McGhee 2015). Its creators begin with the premises that: (a) votes cast for a loser are “wasted”; (b) votes cast for a winner beyond the single vote that puts the winner ahead of the next closest loser are similarly “wasted.” In turn, they devise a very simple statistic based only on party seat and vote shares, without models of simulated or hypothetical quantities, or adjustment for important conditions or relevant vote-generating factors. With only 2 parties and districts equal in voter population $EG = S - 2V$, where S is seat percentage minus 50% and V is vote percentage minus 50%. Quite contrary to intuition, a perfectly fair race is then any 75% to 25% outcome, given that the winning and losing parties waste identical 25% vote shares. If each of 100 districts ended up 75-25, the EG would be 0, regardless of whether party A won every seat, party B won every seat, or they split the seats in any ratio whatsoever.

Jackman (2015), acknowledging the huge challenges of constructing compelling and unique hypothetical data to measure symmetry, sees the simplicity of this statistic as its main virtue, freeing it of “the criticisms that stymied...partisan bias measures.” But this gain is somewhat illusory. The simple arithmetic of the efficiency gap is essentially blind to geography, and divorced from any sense of natural baseline. Cho (2017) lays out some of the pathologies of the efficiency gap, with stylized examples and real data. She deduces that it measures neither bias nor responsiveness, is a poor choice for comparing jurisdictions, particularly if number of seats at play varies, and does not even work well for comparison over time in a given jurisdiction. In exact opposition to Jackman, she concludes that, “complex phenomena like partisan fairness, require nuanced multi-dimensional measures” and that “(f)or ensuring partisan fairness, the efficiency gap is too easily fooled” (2017, 36).

Expert reports in support of various maps (plans), addressing, in part, partisan fairness or symmetry have been submitted by Anthony E. Fairfax, Kenneth R. Mayer, Daryl DeFord, and Christopher Warshaw. Across these reports, one finds calculations and claims based on a variety of common and popular measures of partisan bias or fairness, including efficiency gap scores, declination values, and some calculations based on district normal votes and/or estimated seats-votes curves. It is not surprising that these experts employ those measures, but the sheer volume of calculation should not be seen as conclusive.

For instance, it is noteworthy that the inventor of the declination statistic proposed it, in part, because of misgivings about the efficiency gap, which, he notes “Unfortunately...reduces to proportional representation, an expectation that is not a constitutional right” (Warrington 2018, 39). Declination, however, is, like the efficiency gap, insensitive to whether partisan asymmetry arises by willful manipulation (gerrymandering) or from some other source, such as geographic clustering or compliance with contemporary interpretation of Voting Rights Act requirements. In addressing this concern, Warrington curiously pushes aside the conflation of distinct sources of asymmetry as a “constitutional issue,” rather than a technical point about measurement. Knowing that asymmetries can arise many ways, he proposes measuring asymmetry without any effort to isolate that portion of it that is deliberately created, and then leave to courts the question of whether map makers should be required to match or offset natural differences in how parties fare, assuming that they should not, in any case, enhance them.

In turn, a demonstration that some particular map has better scores than another in *both* efficiency-gap and declination metrics does not really establish superiority in partisan fairness, insofar as both measures capture deliberate partisan bias rather poorly.

A striking point about the vote-seats analyses in the reports is that, for the most part, they make little mention of accumulated uncertainty in estimates and downplay assumptions involved. Thus, Mayer proposes that “the magnitude and direction of partisan symmetry can be read directly from the seats-votes curve” before comparing point estimates. That there are many, many ways to generate that curve is ignored. Fairfax’s Tables 6 and 7 display the various statistics without any standard errors or confidence intervals and the accompanying description ignores uncertainty and assumptions altogether. The most interesting report in this regard is that of DeFord, who nods in the direction of uncertainty without quite acknowledging its extent. Thus, his Figure 6, contrasting a symmetrical function with a less symmetrical one derives from use of presidential vote as a proxy for legislative vote and a uniform swing, which he correctly describes as “one common approach” and not, say, “the best approach.” The uniform swing is not, of course, the only way to model swings, and neither is the presidential vote the actual vote of interest. Figures 10 and 11 extend the analysis by swapping in other estimates of normal vote, none perfect but assumed to have somewhat different (unknown) flaws. None of the curves drawn is drawn with uncertainty, but the accumulation of distinct estimates creates a wider band, and simple visual inspection confirms that the sharp conclusion of his Figure 6 look fuzzier when one considers a larger set of ostensibly justifiable curves. If one asks only “Does the curve pass through the 50-50 point?” then his Figures 10 and 11 answer affirmatively for the plan DeFord defends, and negatively for the rival. But if one asks, “Could one choose a vote model and swing model to ensure that the 50-50 point is within the range of estimates in which one has confidence?” the figures hint that the answer might be yes, with a little determination. In the absence of actual confidence intervals on model predictions, one must guess how these might look. But the normal social-science practice of emphasizing intervals, rather than point estimates, would expand the region covered and endanger the conclusion that one map passes and one fails the 50-50 test.

A subsequent section of the report describes still further analysis, in which the author endeavors to separate out incumbency advantage and to model actual legislative vote in order to deal with the challenge of uncontestedness, and to acknowledge the otherwise neglected point that high correlations between district vote shares from different contests do not assure that vote shares are interchangeable. For the first time, the author also addresses uncertainty in estimation, by repeatedly drawing from the posited data-generating process to generate a set of distinct estimates. The resulting Figures 17 and 18 again suggest that symmetry around the 50-50 point is greater for the maps he recommends than for the rival map to which he compares them. Again, though, what also stands out in the contrast between the leftmost panels of his Figure 17 and the right-most panels of his Figure 18 is that uncertainty about the estimates dampens the contrast. And one can certainly write down models with many other factors beyond incumbency (e.g., spending levels, challenger quality), estimate uncertainty therein, then employ many different swing models, and generate uncertainty about those. Starting with a goal of covering 50-50 or not, one can make modeling choices to ensure the desired result.

Mayer's initial report estimates normal vote from a set of statewide election results, much like the analyses of other experts. His initial report says the analysis computes "party performance using the 2016 and 2020 presidential vote, the 2018 and 2022 U.S. Senate vote, and the 2018 and 2022 Governor and Attorney General vote" (2024a, 23). A second, "corrected" version of the report, replaces that text with the following: "party performance using the 2016 and 2020 presidential vote, the 2018 and 2022 U.S. Senate vote, and the 2022 Governor and Attorney General vote" (2024b, 23-24). Evidently, he decided on some basis to exclude the two state-office contests from 2018. One might assume, from the tone of all of the reports, that it hardly matters which elections one chooses as proxies for the actual legislative elections, because conclusions never change. But perusal of Table A7 from the two different reports shows that the estimated normal Democratic and Republican vote shares for Assembly districts thereby estimated change, sometimes by several percentage points. The two sets of estimates are very highly correlated, at 0.99. Many of the reports trumpet high correlations of that sort in support of the substitution of one for another. But, district by district, the seemingly innocuous change of choice of input data alters estimates a good deal. Estimated Democratic and Republican normal vote shares for the 14th district, for instance, changed from 54.3% D and 43.4% R (+11.1%) (2024a, 47) to 60.2% D to 38.2% R (+22%) (2024b, 47). The 42nd district, originally estimated as 38.9%D and 59.2%R (-20.3%) (2024a, 48) became 37.2% D and 61.8%r (-24.6%) (2024b, 48). The justification for reporting estimates to the tenth of a percentage point is hard to fathom when successive estimates from a slightly tweaked model can move so dramatically. Yet again, one cannot help but wonder about the full extent of uncertainty lurking at each stage of estimation in the analyses.⁵

Warshaw's analyses, like those of Mayer and DeFord, begins with models of normal vote estimated from statewide elections rather than those of primary interest, the actual contests for seats in the state legislature. Like Mayer, he employs many such contests and assures readers that "these statewide races are an excellent predictor of legislative races," elaborating that "presidential election results are nearly perfectly correlated with legislative results in recent years (see, for instance, Table 3 in Jacobson 2021)" (Warshaw 2024, 17). The citation is something of a stolen base,

⁵Having had only a few days to examine so many lengthy reports, I necessarily worked in haste, and could possibly have missed some other change made in the modelling done in the "corrected" report beyond the selection of which elections to use as proxies for actual legislative elections. Unless the corrections were of mistaken transcriptions, the point is the same. There are many ways to write down normal-vote models, and claims of extreme precision, stability and insensitivity to assumptions such as which data to use should not be taken seriously.

as the relevant table in the Jacobson article concerns not state legislative elections, but U.S. House elections. Like DeFord, Warshaw proceeds to further analysis, based on a black-box, but open-source, model implemented by PlanScore software. He notes of those estimates that they add “an additional element to the analysis—the “down ballot” dropoff effect for a given state (which is either neutral, Republican favoring, or Democratic favoring)” and so are “necessarily...different scores for the various partisan bias metrics than the composite results based solely upon prior statewide elections, reported above.” Because the software allows the user to specify incumbency status, these secondary estimates also aim to remove incumbency advantage, as did the analysis I reported above. While Warshaw regards qualitative agreement between the distinct analyses on which is the better map as determinative, one might instead note, yet again, that “I calculated numbers to compare in two different ways” means “out of the thousands of ways one might have done.”

Warshaw’s report also introduces one other form of comparison, as he draws distributions of various statistics for a large set of past maps, not only from Wisconsin, but from other states. These should not be confused with distributions of possible values for present-day Wisconsin, covering the population of feasible maps, as discussed immediately below. Whether the comparison underlying them is sensible or informative depends, in part, on whether the statistics are sensitive to the range of differences across states, such as how distinct are urban, suburban, and rural areas in voting habits, and how the urban, suburban, and rural populations differ in size. Cho’s evaluation of the efficiency gap (2017) noted that it has built-in a sensitivity to jurisdiction size that makes it a poor choice for comparing different legislative chambers. While Warshaw proposes that consistency across distinct statistics establishes “a particularly robust conclusion” (2024, 16), when measures share a flaw, such as inattention to a suitable baseline, agreement between them reveals little.

One final measure is a count of competitive districts, which, arguably, is an interesting criterion, but not really a measure of fairness to parties at all. It too depends on estimation, a point obscured in the reports. One should not be impressed by agreement of a set of statistics, all of which are steeped in assumptions and sidestep or ignore the great difficulties in measuring an elusive trait.

Yet another route for evaluating maps in recent decades has been to situate a given map in a distribution of many possible maps, so that its comparative extremity (or absence thereof) can be determined. Three important points arise. First, despite much technological progress since the first venture into computer-assisted generation of large numbers of maps by Nagel (1965), the fundamental goal of constructing all possible maps remains unsolved. The Holy Grail for redistricting analysis is characterization of the full distribution of possible maps, for a given quality. The building blocks for electoral maps are the smallest division for which population data are made available, such as census blocks. In most large-scale cases, like states, with thousands of block groups, the number of possible maps is astronomical—not merely large, but so large that brute force computation is fundamentally impractical even with very fast super computers. Most of the debate about using powerful computers to construct maps turns on whether there is a feasible way to produce a very large set of maps that is plausibly or demonstrably a random sample from the unknown complete distribution. Random samples are extremely useful, but not quite as informative as actual distributions, because they generate probabilistic claims, rather than deterministic ones. Moreover, and more importantly, it is not yet resolved whether anyone can prove that an estimate of the unknown true distribution of maps is, truly, random (see, e.g., Cho and Liu 2019, Cho and Rubinstein-Salzedo 2019).

Second, even if the huge technical problem of constructing distributions were somehow solved, debates would not thereby end. Ultimately, choosing maps is inherently about prioritizing some criteria over others. With the at-present-only-hypothetical ability to consult the full set of possible maps, one could promote a given map as, say, “the most partisan-neutral map possible, according to measure X of neutrality, among all maps that also have k districts which are expected to be competitive by model Y , and j districts that are more than p percent likely to return at least q African American representatives, and that alter none of the prior districts by more than w percent in metric C .” Such claims could be verified, which is not the case now. But there is not a single best algorithm for electoral map-making because the choices of which qualities to emphasize, what thresholds appeal, and, in most cases, even how to measure them are all political rather than merely technical.

Powerful computers have made it far easier to draw large numbers of maps. They have probably made it a little easier to concoct maps with express political purposes, that is, to gerrymander in some fashion. They have not, and could never, “solve” the problems of redistricting.

A third point about any analysis grounded in estimated distributions of the full set of possible values (assuming a satisfactory metric) applies in particular to partisan neutrality. If, in a rather blue or red state, it is possible to draw a perfectly purple map, is it neutral to do so? The whole notion of institutions being neutral to parties is surely conditional on the context. Neutral more naturally means engaging in equal treatment rather than equitable treatment. As noted above, Warrington’s defense of the declination statistic is that one should measure asymmetry in party performance, without worrying about its source. But if the source is, in some degree natural (human geography) or conditional from pursuit of other criteria, the asymmetry is probably less objectionable.

And, finally, to return to where I began, the most important rights in regard to political institutions are enjoyed by individuals, not electorates.

4 Voter Preferences On Mapping Criteria and Map Types

Voters in fact seem to embrace multiple criteria for what constitutes a good map, which might bear on how important partisan neutrality should be among a set of criteria that can possibly be in tension.

Surveys about redistricting, preferred process or outcomes, are scarce, because many public-opinion researchers regard the topic as too arcane for all but the most highly politically engaged. However, in both a 2020 national survey and a 2023 Illinois-only survey, respondents were asked to rank a set of possible criteria for electoral maps. The 2020 questions were part of that year’s Cooperative Election Study, fielded in October 2020 by YouGov, to a representative sample of 1,000 adult Americans responding online. The March 2023 survey was commissioned by CHANGE Illinois, and again fielded by YouGov, with 1,000 Illinois registered voters who reported an intention to vote in 2024 as respondents.

The precise wording of the particular questions was, “After each decennial census is completed, all states redraw the districts they use for elections to the state legislature, and all states with more than one U.S. Representative redraw their U.S. House districts. Every state requires its districts to have nearly identical populations, but there are many other criteria for what constitutes

a fair or good set of districts (an “electoral map”). Please rank in importance the following goals for making a new map, from highest (most important to you) to lowest (least important).” The goals they were asked to rank, which were randomly ordered, were the following (with nicknames that did not appear in the surveys shown in parentheses).

- Districts should take relatively simple shapes. (compactness)
- Boundaries should follow existing country and city lines as much as possible. (congruence)
- As many districts as possible should be about equally balanced between Democrat and Republican voters, for competitive elections. (competitiveness)
- The overall percentage of seats won by each major party should be about the same as its overall percentage of the total vote. (party proportionality)
- Towns and neighborhoods that have a lot in common should be put in the same district, as much as possible. (communities (of interest))
- The proportion of legislators that is Black should be about the same as the proportion of the population that is Black.(Black proportionality)
- The proportion of legislators that is Spanish-speaking should be about the same as the proportion of the population that is Spanish-speaking. (Latino proportionality)
- New maps should resemble prior maps as much as possible, for continuity. (continuity, 2023 survey only)

In both surveys, at least 5% of respondents picked each possible rank for each criterion, so it would be fair to say that there is not a powerful consensus on which should prevail. In the national sample in 2020, party proportionality and congruence with other boundaries had the highest priority (lowest mean ranking, where lower numbers signify higher importance, i.e. top or first-place ranking versus bottom or seventh-place ranking). They were ranked first by 19% and 22% respectively, and the mean rankings for these criteria were 3.41 and 3.43, below 3.67 for compactness in third place and 3.76 for competition in fourth place. Communities of interest and racial proportionality lagged further still behind, the latter not being priorities even of those respondents from the particular racial group (Gaines 2021).

Responses from Illinois registered voters in 2023 were broadly similar, with congruence edging out party proportionality for top spot, but those two plus compactness and competition being statistically indistinguishable, and prioritized more highly than racial proportionality, communities of interest, or continuity. (In the 2023 Illinois data, one difference from the 2020 national data was a higher priority for Black proportionality among Black respondents.)

Notwithstanding the points made above about the great difficulty in ascertaining whether any given map would be comparatively neutral in its seat-awarding performance, given various unobserved vote-share scenarios, the public seems to have some affinity for approximate proportionality. These survey items, it should further be noted, did not present the criteria as being in tension, possibly or necessarily. And even though “continuity” had the second highest (that is, worst) ranking in the Illinois study, its appeal is perhaps subtle, and difficult to separate from “communities of interest” and congruence (which, when implemented, creates continuity).

Individuals residing in newly drawn districts with little resemblance to their prior districts can face somewhat higher costs of mobilizing for political action. Empirical studies confirm that

boundary shifts can lower public familiarity with candidates and, in turn, induce abstention and disengagement (e.g., Hayes and McKee 2009, 2012; Winburn and Wagner 2010). On the flip side, congruence between electoral boundaries and pre-existing county and municipal boundaries somewhat reduces transaction costs for individual political participation.

Voting is necessarily a costly activity. Even in the absence of poll taxes or other obstacles to voting, citizens who opt to express their political preferences on ballots incur opportunity costs, particularly if they devote time to evaluation of candidates in advance of voting. For a variety of reasons, these costs tend to be higher in the United States, where elections are comparatively frequent and ballots are comparatively long, providing many choices across a variety of offices. Much public debate on election administration relates to how best to reduce voting costs, without negatively affecting other desirable features in elections, particularly integrity and security, but also efficiency and economy for administrators. Across a range of logistical issues, continuity is recognized as a benefit for voters. Changes in location of in-person voting sites, for instance, whether motivated by population shifts, cost reduction, or even public-health emergency, are understood to impose costs on citizens (Vasiligambros, Levine, and Rebala 2020). Likewise, such discontinuities as changes in voting procedure and/or mode clearly impose costs on voters and, accordingly, are justifiable primarily if they are also expected to deliver tangible benefits in ease, security, or another identifiable goal for elections.

Somewhat less noticed is that changes in electoral districts can also increase the costs of voting. Indeed, much political engagement, such as campaigning and participating in other “grassroots” political activity, is potentially disrupted by redrawing of boundaries, which shuffle individuals into new blocs and can thereby demolish the justification for cooperation across individuals or groups. This point is complicated by the fact that the multiplicity of electoral offices in the United States ensures that given individuals will normally reside in many electoral districts, for seats in the U.S. House, state legislative chambers, municipal or county offices, and so on. Nearly all discussion of district and map traits is done office by office, ignoring that complexity in representation, just as much work on partisanship ignores the signs that it exerts force differently for different elective offices. It could be that Americans, with many levels of government and individual representatives to petition, are unusually adept at shifts in definitions of electorates and the composition of affected people. All the same, disruption of boundaries seems far more likely to hamper than to assist citizen organization.

That ordinary voters hold a variety of views on what makes a good electoral map is not widely appreciated. A further finding from these studies is that those who describe themselves as strong partisans do not, overwhelmingly, prefer maps that are expected to display asymmetry that favors their own party in how they convert votes into seats (Gaines and Kuklinski 2010, Gaines 2021). Partisans, even strong ones, do not fully match parties in the single-mindedness of their interests. Partisan neutrality, as applied to electorates, is both somewhat popular and quite nebulous.

Education

Ph.D., Stanford University (1995)
Incumbency Advantage and the Personal Vote in the Anglo-Atlantic Democracies
(Douglas Rivers, John Ferejohn, David Brady, Geoffrey Garrett)
A.M., Stanford University (1989)
B.A. (Honours), University of British Columbia (1988)

Academic Appointments

Department of Political Science, University of Illinois at Urbana-Champaign
Professor (2011-); Associate Professor (2001-11); Assistant Professor (1995-2001)
Institute of Government and Public Affairs, University of Illinois
Honorable W. Russell Arrington Professor in State Politics (2023-),
Senior Scholar (2020-22); Professor (2011-19); Associate Professor (2003-11)
European Union Center, University of Illinois (2005-)
Cline Center for Democracy, University of Illinois
Merriam Professorial Scholar (2012-14)
Hoover Institution
W. Glenn Campbell and Rita Ricardo-Campbell National Fellow and Arch W. Shaw
National Fellow (2011-13)
Katholieke Universiteit Leuven, Belgium
Visiting Scholar, Department of Management, Strategy, and Innovation (summer 2019);
Visiting Scholar, Department of Applied Economics (summers 1997, 1999)
School of International Relations and Public Affairs, Fudan University, Shanghai, China
Guest Instructor, (summer 2002)

Research Interests

elections, electoral institutions and laws, public opinion, survey methods, political behaviour,
statistical methods, legislatures, game theory

Teaching Experience

Undergraduate

1. Introduction to Political Science
2. Introduction to Rational-Choice Analysis of American Politics
3. Introduction to Political Research (Statistics for Political Science)
4. Introduction to American Government
5. Political Behavior
6. Elections and Electoral Behaviour
7. Government and Politics of the United Kingdom
8. State Government in the United States

Graduate

1. Statistical Methods in Political Science I (Introduction)
2. Statistical Methods in Political Science II (Regression)
3. Statistical Methods in Political Science III (Topics)
4. Game Theory I: Introduction
5. Game Theory II: Advances and Applications
6. Panel Data Analysis*
7. Contemporary Theories of Voting Behaviour
8. Research Practicum in Civic Leadership (MA)
9. Research Design

* Interactive live-video course to U. Illinois, U. Minnesota, Ohio State U., and U. Wisconsin

Faculty, CIC British Parliamentary Internship Programme, 1997–2011

Supervised internships and research projects for students from U. Illinois, U. Michigan, U. Wisconsin, and Purdue (select years) in London, mostly in the UK House of Commons

University of Illinois Political Science Graduate Student Top Mentor Award, 2003, 2007

4.4	Gerrymandering Index	54
5	What is a fair map?	54
5.1	How do you properly measure partisanship?	55
5.2	How important is competition?	58
5.3	How should we define a fair map?	60
5.4	What is the role of partisanship in an single-member district system?	64

1 Introduction and Executive Summary

In this report, I was asked to evaluate the various maps submitted for this Court's consideration. Because of the relatively short turn-around, I was not able to offer a point-by-point rebuttal to all expert reports. In the course of evaluating these maps, I received WISE-District reports run by legislative staff for each proposed plan. They are attached to this response report as Exhibit A.

In summary, this report concludes:

- The various proposed maps move large numbers of individuals from even-numbered senate districts to odd-numbered districts;
- The various proposed maps appear to be drawn with indicia of partisan intent;
- The various proposed maps offer up competing normative visions of what constitutes a fair map.

2 Movement of individuals from even- to odd-numbered districts

First, I was asked to examine how many individuals were moved from an even-numbered Senate district to an odd-numbered Senate district. I was then asked to examine the partisanship of the individuals who were moved.

To accomplish this, I filtered the total set of Wisconsin census blocks to include only those that were placed into an even district under the existing plan. I was then able to impose a second filter on that subset of blocks, narrowing the grouping further to include only those who were also placed into an odd district under each of the various proposed remedial maps.

I then was able to utilize a shapefile from the Redistricting Data Hub that projects Wisconsin's votes to the Census Block level (this is the same data used in my initial

Partisanship and Proposed Maps: Senate — 2

report). I could then calculate the number of votes cast in these moved blocks for each candidate in the presidential elections, as well as the 2022 gubernatorial race (Other elections could easily be calculated from the data). Those numbers are reported below for each map.

Thus, for example, the Clarke map shifts 697,154 individuals from an even-numbered district to an odd-numbered district. Of those individuals, 233,064 voted for former President Donald Trump, while 170,944 voted for President Joe Biden. Thus, 57.69% of the voters in these census blocks voted for former President Trump. 56.36% voted for Tim Michels in the 2022 gubernatorial election.

Figure 1: Movement of residents and voters from even- to odd-numbered districts, by plan

Proposed Map	Population Shifted	Trump Vote Shifted	Biden vote shifted	R Voters, 2022 Gov., Shifted	D Voters, 2022 Gov., Shifted	Trump %	R Gov. 22 %
Clarke	697,154	233,064	170,944	186,910	144,666	57.69%	56.37%
Governor	671,543	209,801	172,467	167,775	146,013	54.88%	53.47%
Johnson	431,396	110,220	119,143	85,840	100,414	48.05%	46.09%
Senate Dems	600,979	168,089	159,983	131,665	133,303	51.24%	49.69%
Wright	750,208	270,360	162,907	218,319	137,984	62.40%	61.27%
Legislature	141	24	57	24	64	29.86%	27.30%

3 Partisanship and Proposed Maps: Senate

3.1 SMC Ensembles

In my initial Report, I described how I utilized the Sequential Monte Carlo (SMC) technique to create randomly generated maps to explore the political geography of Wisconsin and to look at what sorts of outcomes we might expect from a draw of Wisconsin's maps without respect to politics.

Because we now have actual maps to view, we can examine how closely these maps hew to Wisconsin's natural political geography. To do this, I simply calculate the partisan

Partisanship and Proposed Maps: Senate — 3

vote share in each district for each plan, and then plot the values against the simulations produced in the previous report. Thus, we can get a sense of the role partisanship played in the drawing of each map.

We can start, for example, with the Johnson Map. We plot 50,000 dots for each district, so in a 99 – district map we are plotting close to 5,000,000 dots. Needless to say, this requires a lot of computational time, even from a very fast computer. Because of this, I only employ President Joe Biden’s vote share as a measure of partisanship for the simulations, although other metrics could be produced with some minor tweaks to the code.

We can first examine the Johnson plaintiffs’ maps:

Figure 2: Johnson Sen. Map, vs. Ensemble, SMC

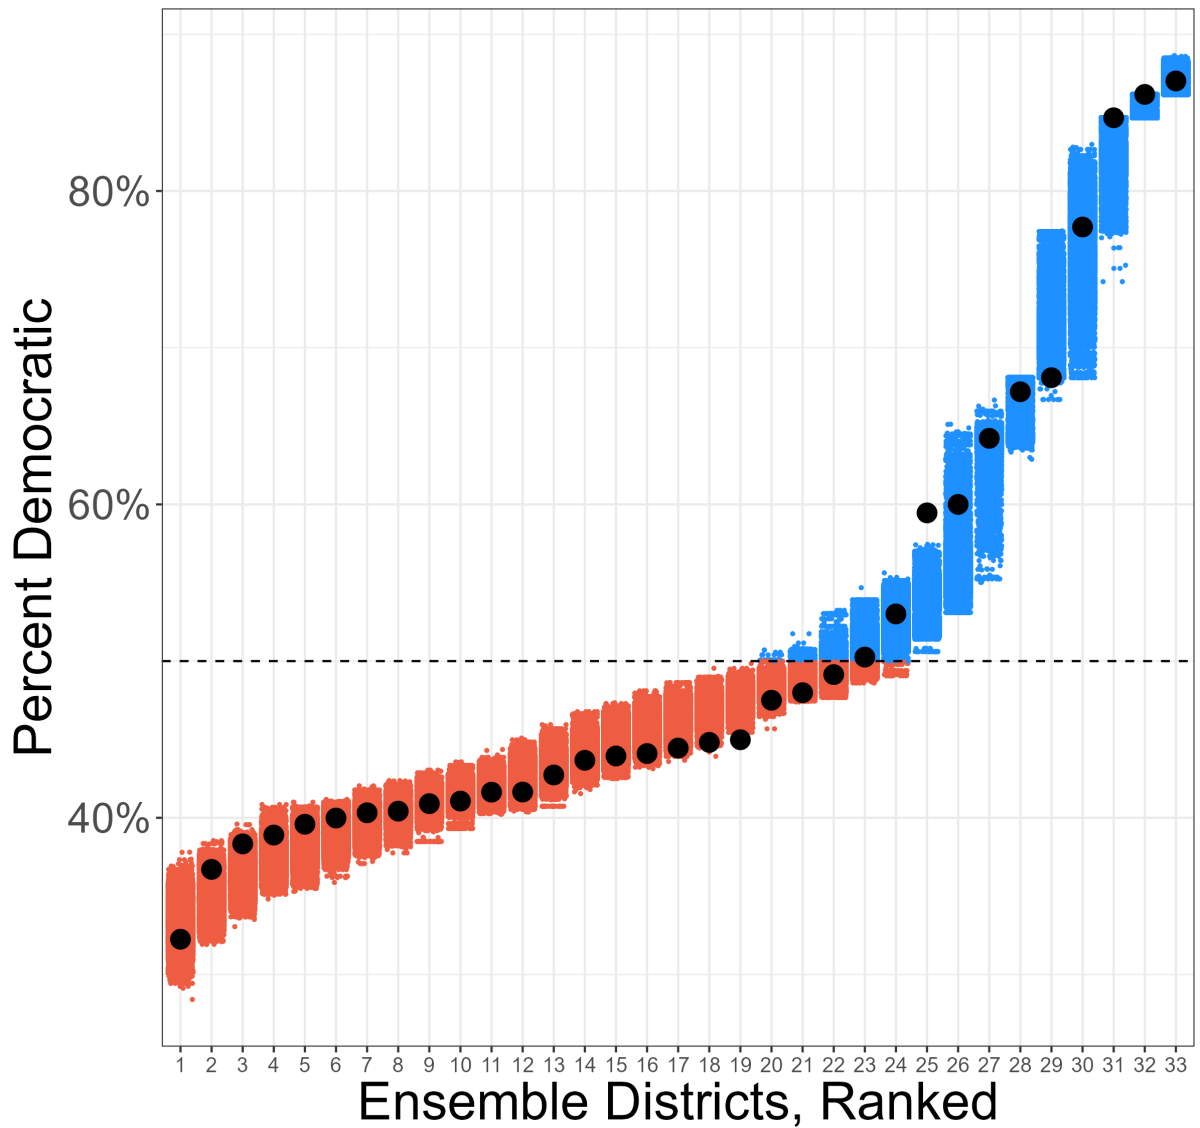

The most Republican district is denoted by a black dot in the left column, the second-most Republican district is denoted by a black dot in the second-left column, and so forth. As you can see, the Johnson map closely resembles maps drawn without respect to politics, but with respect for population equality, Milwaukee’s VRA districts, county boundaries, and compactness. Almost all of the dots fall within the ranges you would expect. There is some work toward Democrats’ benefit near the 50%-50% mark, but overall there is no clear pattern that would suggest a map is being drawn overall to

benefit one party or the other.

Likewise, the Legislature’s map mostly falls within the boundaries of what we would expect from a politics-free map, though there is some work toward Republicans’ benefit near the 50%-50% mark. Overall this is a map that does not excessively benefit one party or another, but rather reflects the natural partisan sorting in the state.

Figure 3: Legislature’s Sen. Map, vs. Ensemble, SMC

The remaining maps, on the other hand, show significant deviations from what

Partisanship and Proposed Maps: Senate — 6

we would expect from maps drawn free of partisanship. All of them show Republican vote shares pushed down toward the bottom of their expected ranges when we would expect heavily Republican districts. This represents the packing of Republican voters into districts.

By artificially increasing the Republican vote share in these districts, Democratic voters are freed up to create more Democratic-leaning districts. This is how all of the remaining maps, save for the Clarke Map, are able to create 17 senate districts carried by Joe Biden: By fighting Wisconsin's political geography.

Figure 4: Clarke Sen. Map, vs. Ensemble, SMC

Figure 6: Senate Democrats' Sen. Map, vs. Ensemble, SMC

Sen. Dem. Sen. Map vs. Ensemble

Figure 7: Wright Sen. Map, vs. Ensemble, SMC

3.2 Gerrychain Ensembles

As an additional robustness check, I've run a separate set of simulations using a different technique. I could not have run this for the initial report, because it typically utilizes existing districts as its starting point. This technique, known as recombination, is maintained by the Metric Geometry and Gerrymandering Group and was developed by Daryl DeFord, Moon Duchin and Justin Solomon. *See, e.g.,* <https://github.com/mggg/GerryChain>. *See also* Daryl DeFord, Moon Duchin, and Justin Solomon, Recombination:

A Family of Markov Chains for Redistricting, available at <https://hdsr.mitpress.mit.edu/pub/1ds8ptxu/release/5>.

The concept behind this technique is that gerrymanders are fragile. If the boundaries are altered much, the partisanship of the district is altered significantly. Think of it this way: if a line on a map perfectly separates Republican precincts from Democratic precincts into Districts A and B, then swapping out precincts randomly between Districts A and B should result in the Republican vote share in A and the Democratic vote share in B dropping quickly.

In other words, there are only so many ways to draw a gerrymander, but many ways to draw a map that reflects the state's geography. Or, if you prefer, there are only so many ways to create a tidy room, but it doesn't take much to make it messy. If you move a bunch of clothes in an otherwise-clean room randomly, it's unlikely you'll have a clean room in the end. However, randomly moving around clothing in a messy room isn't likely to create a clean room; its "messiness" should remain fairly stable.

Likewise, moving around precincts randomly in a map that reflects the state's geography is more likely to create more maps that reflect the state's geography than it is to create a gerrymander randomly. Gerrymandering is typically an intentional process, and multiple random perturbations of gerrymandered districts shouldn't create a map that is also gerrymandered.

Gerrychain takes a proposed map, and begins moving precincts around by splitting districts and then recombining them into new districts. If the map was drawn without respect to politics (in other words, it was messy) then recombining the districts (moving around random items of clothing in the room) shouldn't alter the politics of the districts that much. If, however, the districts were artificially sorted by politics, shifting the districts should result quickly in a map with very different politics.

You can see the results below for the senate maps (Gerrychain utilizes boxplots to show the ensemble distribution rather than dotplots). The red dots represent the various proposed maps. These use presidential vote share to reflect district partisanship. Once

again, the Johnson map looks like a map drawn without respect to partisanship; while it helps Democrats a bit around the 50-50 mark, it does so within the bounds of politics-neutral maps. The legislature’s map has stronger deviations than the Johnson map, but they are still fairly subtle. The other maps maps, however (I was unable to make the Clarke map converge consistently), all contain substantial deviations from what a neutral draw would look like, particularly near the 50-50 line.

Note that, because I wanted to freeze VRA districts drawn in response to *Baldus*, however defined in a particular map, in place, the Senate simulations only have 30 districts and the Assembly simulations only have 90 districts. Also, via a quirk of GerryChain, District 1 is represented as District 0; District 16 is therefore the district that determines control for the Senate, while District 49 determines control for the House.

This is true if you use 2020 presidential data to measure partisanship.

3.3 Qualitative Examination of Maps

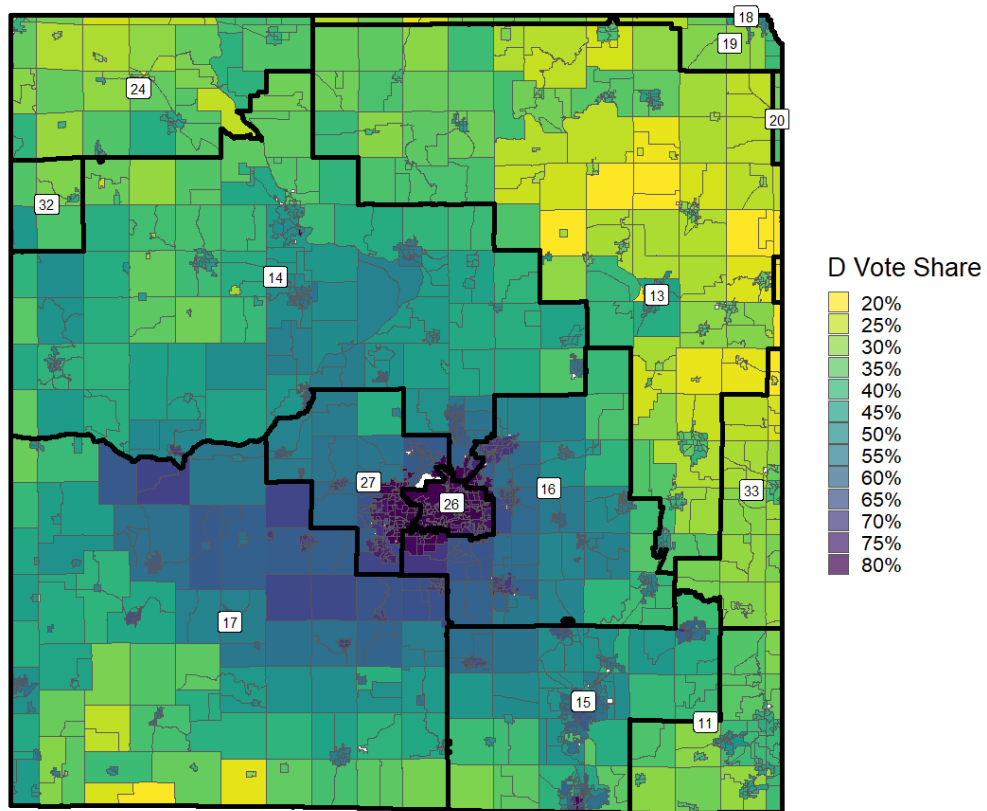

The proposed maps typically accomplish strong scores on the traditional redistricting criteria cited by this Court by drawing reasonably configured, compact districts in heavily Republican areas, where the configuration does not matter much (i.e., a Republican district will be drawn no matter what). The maps then make select choices that would not flow naturally from the state’s political geography in an attempt to create more Democratic districts; these choices are then hidden in statewide summary statistics by the naturally occurring Republican and Democratic districts elsewhere in the map.

To get a sense of how this is accomplished, consider the Governor’s Senate Map. The following map shows the area around Madison, Wisconsin, with the precincts shaded by vote share. As with the 2022 map, it creates three heavily Democratic districts around Madison, and an additional Democratic district around Janesville. It then, however,

creates an additional Democratic-leaning district to the north of the city. As drawn, this district gives Biden 51.2% of the vote to Trump's 47.2%. While the district is generally compact (though it does split four counties), one may note the arm reaching into the City of Madison. That arm gave Joe Biden 65% of the vote; without it, Donald Trump narrowly won the district.

Moreover, had some of that population from Madison instead been used to repair the county splits in Columbia and Adams counties, leaving a smaller split in Dane County, Donald Trump would have carried the district handily. These "tweaks" appear all over the map and create the above pattern that reflects the "DNA of a gerrymander." See also Gregory Herschlag et al, "Quantifying Gerrymandering in North Carolina: Supplemental Appendix." 7 *Statistics and Public Policy* 30 (2020) (referring to this pattern as the "signature of gerrymandering").

Figure 19: Governor’s Sen. Map, Madison Area

© OpenStreetMap contributors

We see similar choices in southeastern Wisconsin. For example, in the Milwaukee area, District 8 carefully avoids the more heavily Republican precincts in Ozaukee and Washington counties, creating a marginally Democratic district in the process (the Senate Democratic map employs basically the same approach to this district). Likewise, the 21st bifurcates Racine, traversing lightly populated, heavily rural areas, before moving into the inner suburbs of Milwaukee, and even taking in a portion of the city itself. The Wright map takes a similar approach, albeit with a more heavily distorted district.

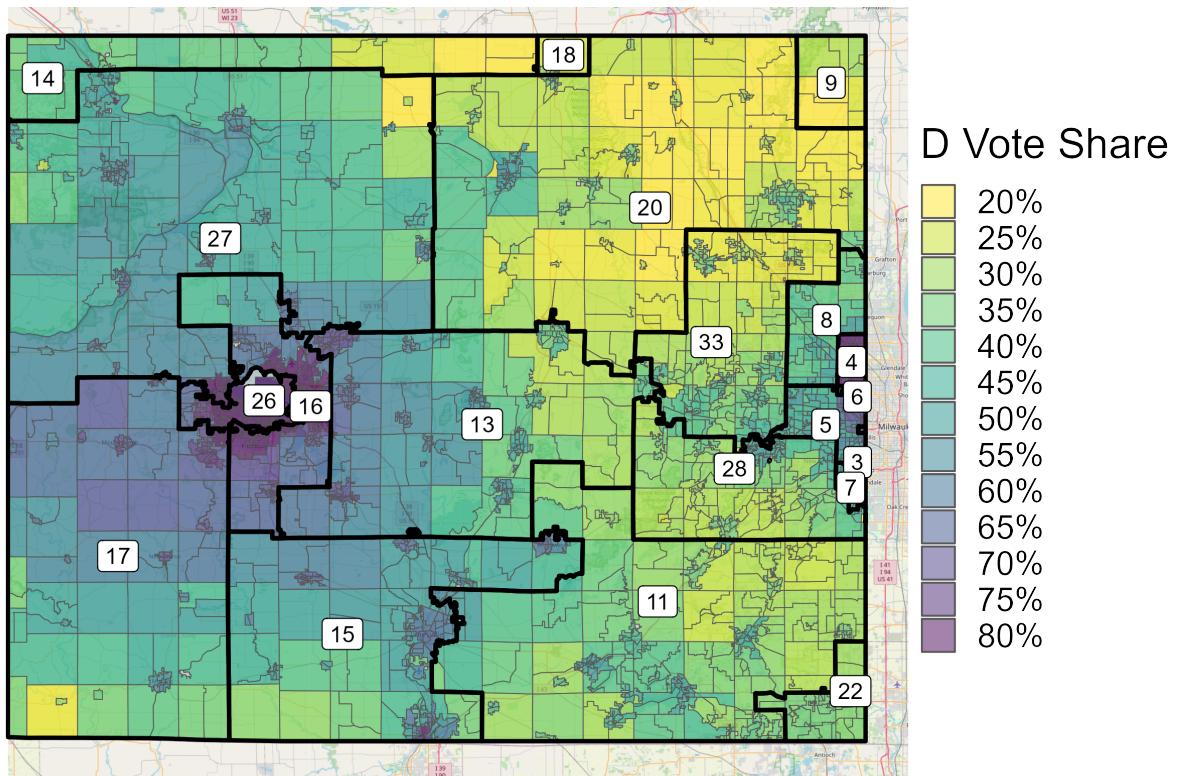

Figure 20: Governor’s Sen. Map, Milwaukee Area

© OpenStreetMap contributors

Likewise, the Senate Democrats’ map creates an additional marginally Democratic district east of Madison by taking heavily Democratic places like Sun Prairie and Stoughton, and stretching those districts eastward, away from the city, into more Republican Jefferson County, and then over to Waukesha county. District 27 “fracks” Dane County (splitting it more than once) by sending an arm into overwhelmingly Democratic Middleton, and then a second arm into Democratic portions of northeastern Dane.

Figure 21: Senate Democrats' Sen. Map, Milwaukee

© OpenStreetMap contributors

The Wright map takes a similar approach, dipping into the City of Madison itself to make District 14 a Democratic district before extending out into the Republican countryside. District 27 is even more extreme, taking in large portions of northern Dane County (including a part of the City of Madison) before extending out into the countryside. District 32 also reaches well into Madison, before extending to the southwest corner of the state.

Figure 22: Wright Sen. Map, Milwaukee

3.4 Gerrymandering Index

Of course, eyeballing deviations on dotplots may not answer the question “how much overall gerrymandering is too much?” To do this in a more rigorous manner, I have typically employed the “gerrymandering index,” proposed by Bangia et al (2017) and endorsed by McCartan & Imai in their initial paper setting forth the algorithm used to generate the districts in this report. See Cory McCartan & Kosuke Imai, “Sequential Monte Carlo for Sampling Balanced and Compact Redistricting Plans,” at 25, available at <https://arxiv.org/pdf/2008.06131.pdf>.

It is conceptually similar to the idea of root mean squared error (used throughout statistics). To calculate the index, we take each of the 50,000 simulated maps and rank the districts from most heavily Democratic to least heavily Democratic. We then average Democratic vote shares across ranks. This tells us, generally speaking, what percentage of the Democratic vote share we would expect the most heavily Democratic district to have in a map drawn without respect to politics, what we would expect the second-most

heavily Democratic to have, and so forth.

Of course, some areas might be conducive to a wide range of partisan outcomes depending how the map is drawn. Other areas, like downtown Madison, are so heavily Democratic that the districts that are drawn there are likely to vary very little in their partisan makeup. Put differently, we might be very surprised, due to simple geography, if a map's most Democratic district varies from that average by more than a few points; we might be less surprised if some districts in the middle of the distribution exhibited more variability.

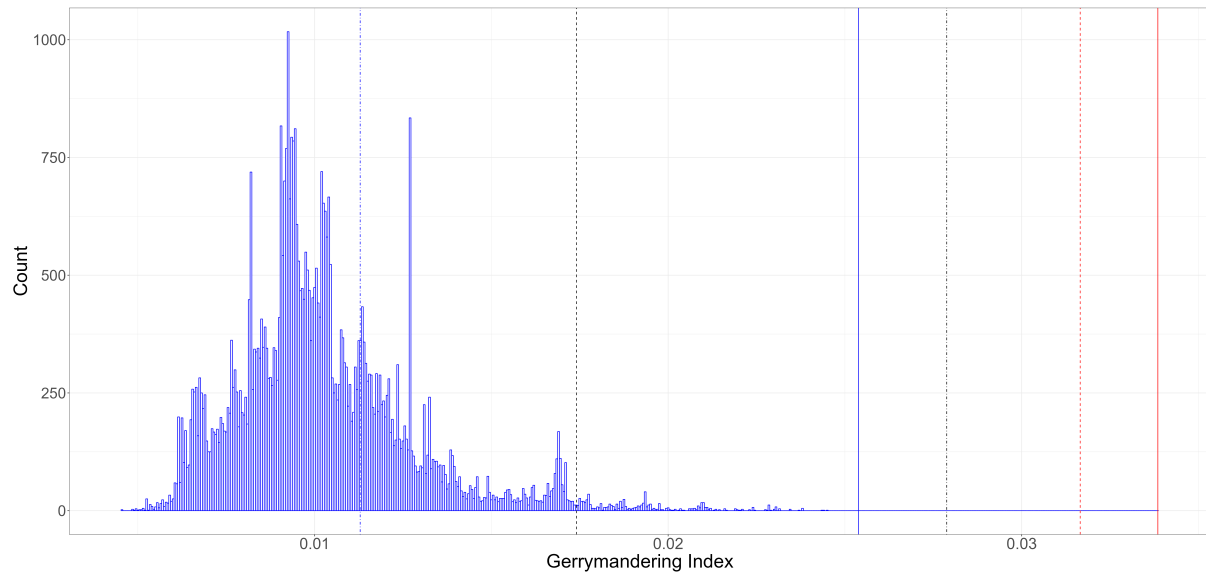

To help account for this, we then calculate the deviations in each plan in the ensemble from the mean for each "bin." To make this less abstract: the most heavily Democratic district in the ensemble, on average, gives the Democrats around 90% of the vote. A district in the ensemble whose most heavily Democratic district was 92% Democratic would have a deviation of 2% for that rank, while one whose most heavily Democratic district was 97% Democratic would have a deviation of 7%, and so forth. To emphasize large deviations (and to make them all positively signed) these values are then squared. These values are then added together to give us a sense of how far the map deviates overall from the ensemble mean in each district.

In simplified terms, this gives us the total deviation from the ensemble for all the districts in the plan, while giving more weight to particularly large misses. The square root is then taken, which effectively puts everything back on a percentage scale. This gives us a weighted average deviation from the mean for each plan in the ensemble. We can then engage in a similar exercise for the various proposed maps.

In the following histogram, I've plotted the distribution of gerrymandering indices for the ensembles. I've also denoted the values of the gerrymandering indices for the various proposed plans with vertical lines.

Partisanship and Proposed Maps: Assembly — 29

Figure 23: Gerrymandering indices of ensemble, versus proposed State Senate maps. Blue dashed line = Johnson Map; Black dashed line = Legislature’s Map; Solid blue line = Governor’s Map; Black dotted line = Clarke Map; Red dashed line = Wright Map; Solid red line = Senate Dems’ Map

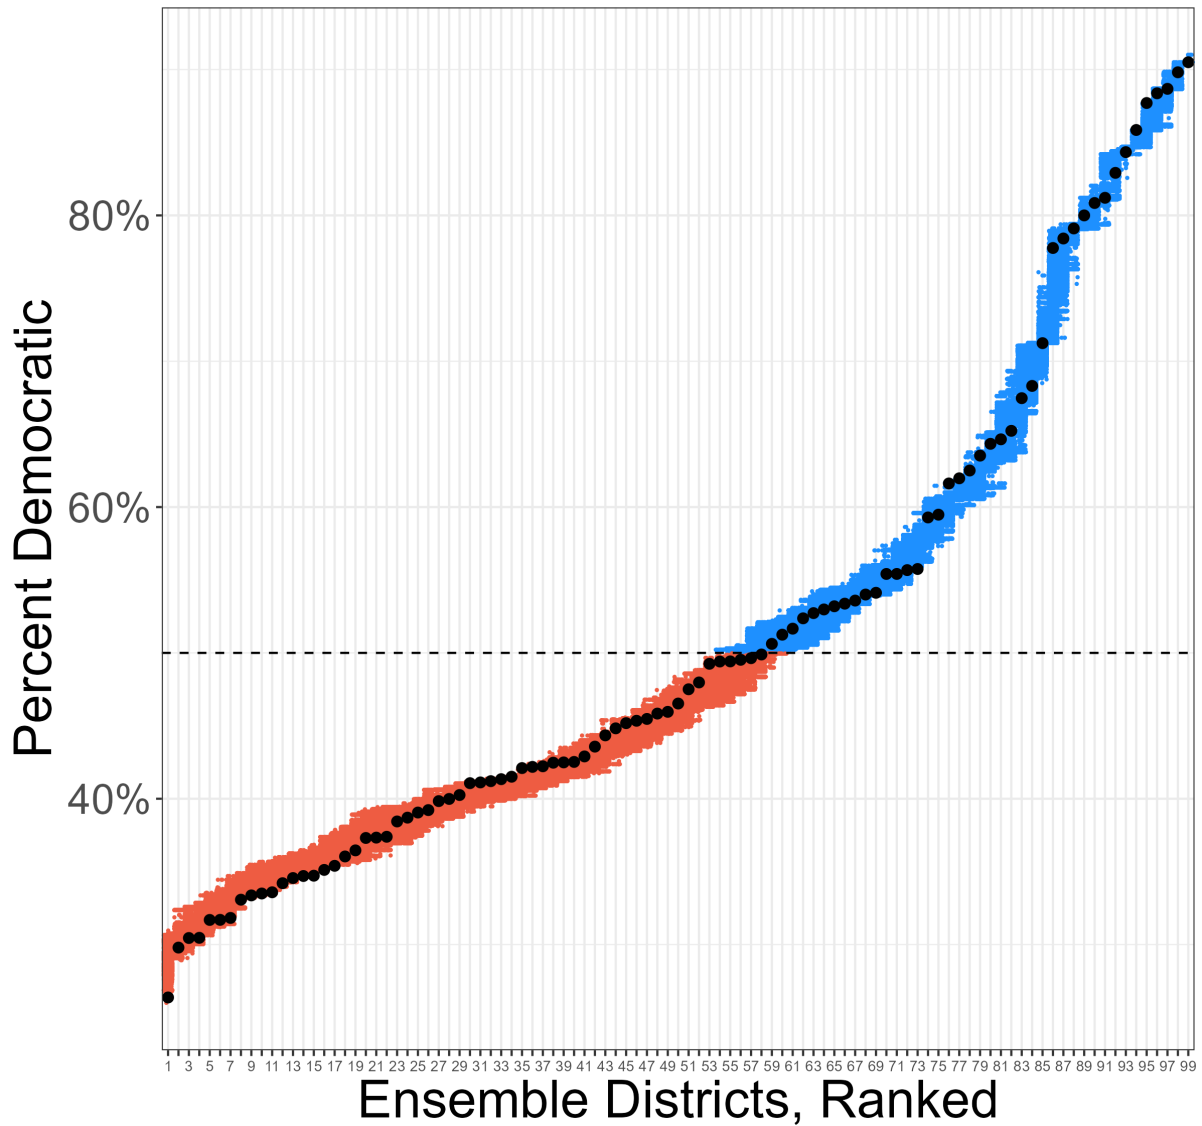

The Johnson map falls almost in the center of the distribution for a map drawn without respect to politics, while the Legislature’s map falls within the range of that distribution, although it is further on the tails. The remaining maps – the Governor’s Plan, the Clarke Plan, the Wright Plan, and the Senate Democrats’ Plan – all deviate substantially from what we would expect to see in a politics-neutral map.

4 Partisanship and Proposed Maps: Assembly

4.1 SMC Ensembles

The Assembly maps exhibit the same basic pattern. The Johnson Map again appears to be a map drawn without respect to politics, with districts following the expected results from a politics-free map closely.

Figure 24: Johnson Assembly Map, vs. Ensemble, SMC

Likewise, the Legislature’s Assembly map hews closely to what we would expect from a politics-free map, with some benefit for Republicans near the 50-50 line.

Figure 25: Legislature’s Assembly Map, vs. Ensemble, SMC

The remaining four maps, on the other hand, all deviate substantially from what we would expect from politics-free maps. They do so generally by pushing the Democratic vote share downward in heavily Republican areas and moderately Democratic areas, freeing up Democratic voters to push into otherwise-swing or modestly Republican districts.

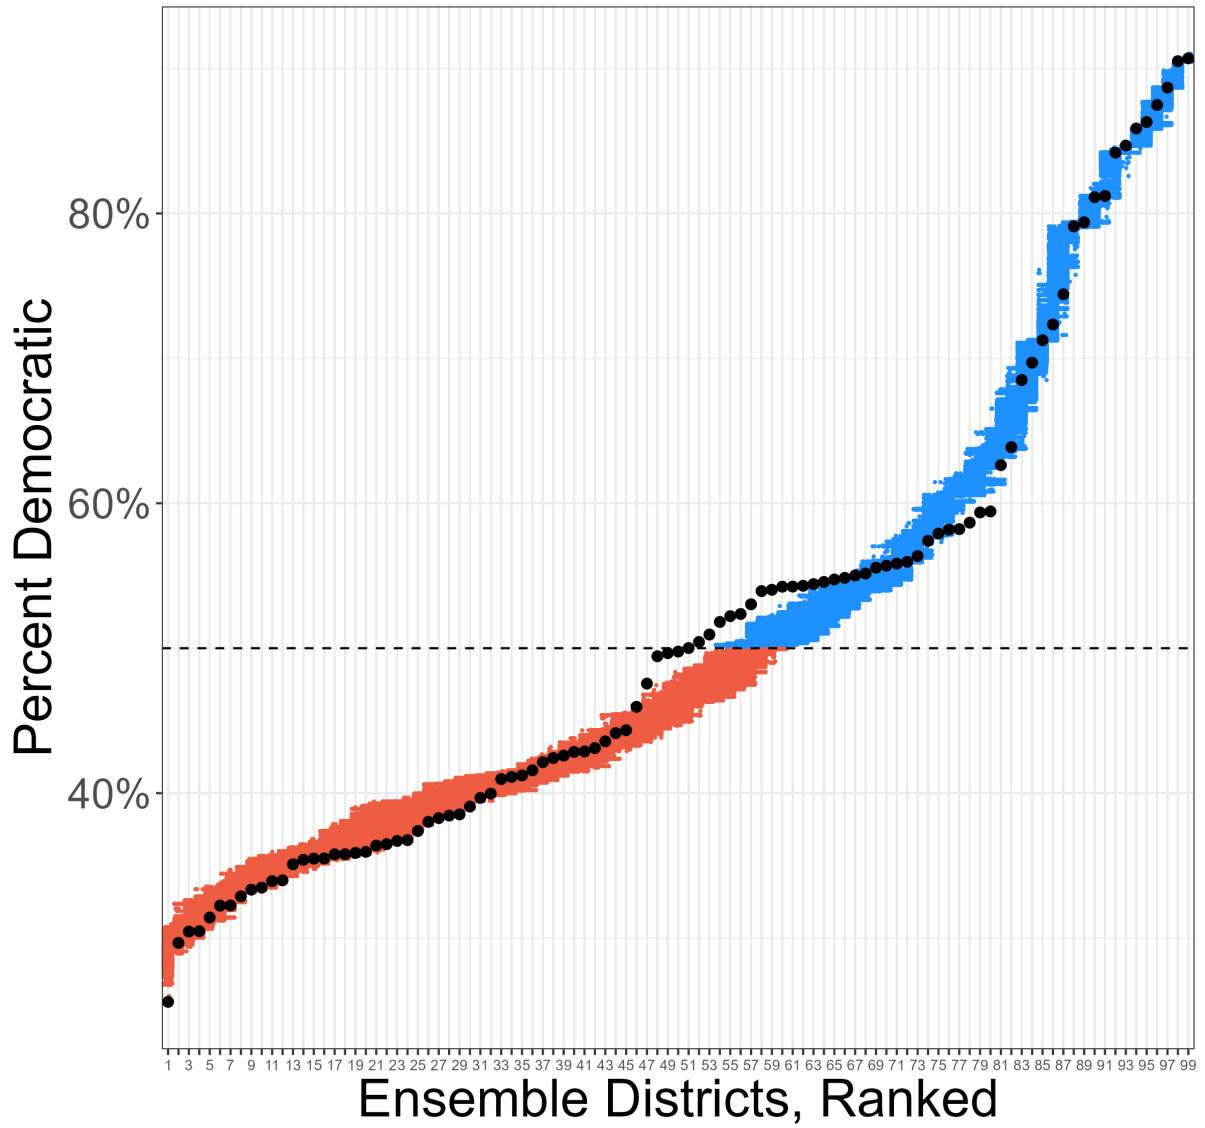

Figure 28: Senate Democrats' Assembly Map, vs. Ensemble, SMC

Figure 29: Wright Assembly Map, vs. Ensemble, SMC

4.2 Gerrychain Ensembles

Once again, I employ the Gerrychain Ensembles and find that the Johnson Map hews closely to the underlying political geography of the state, the Legislature’s map deviates somewhat, and the other maps deviate heavily. This is true if you use 2020 presidential data to measure partisanship.

4.3 Qualitative Examination of Maps

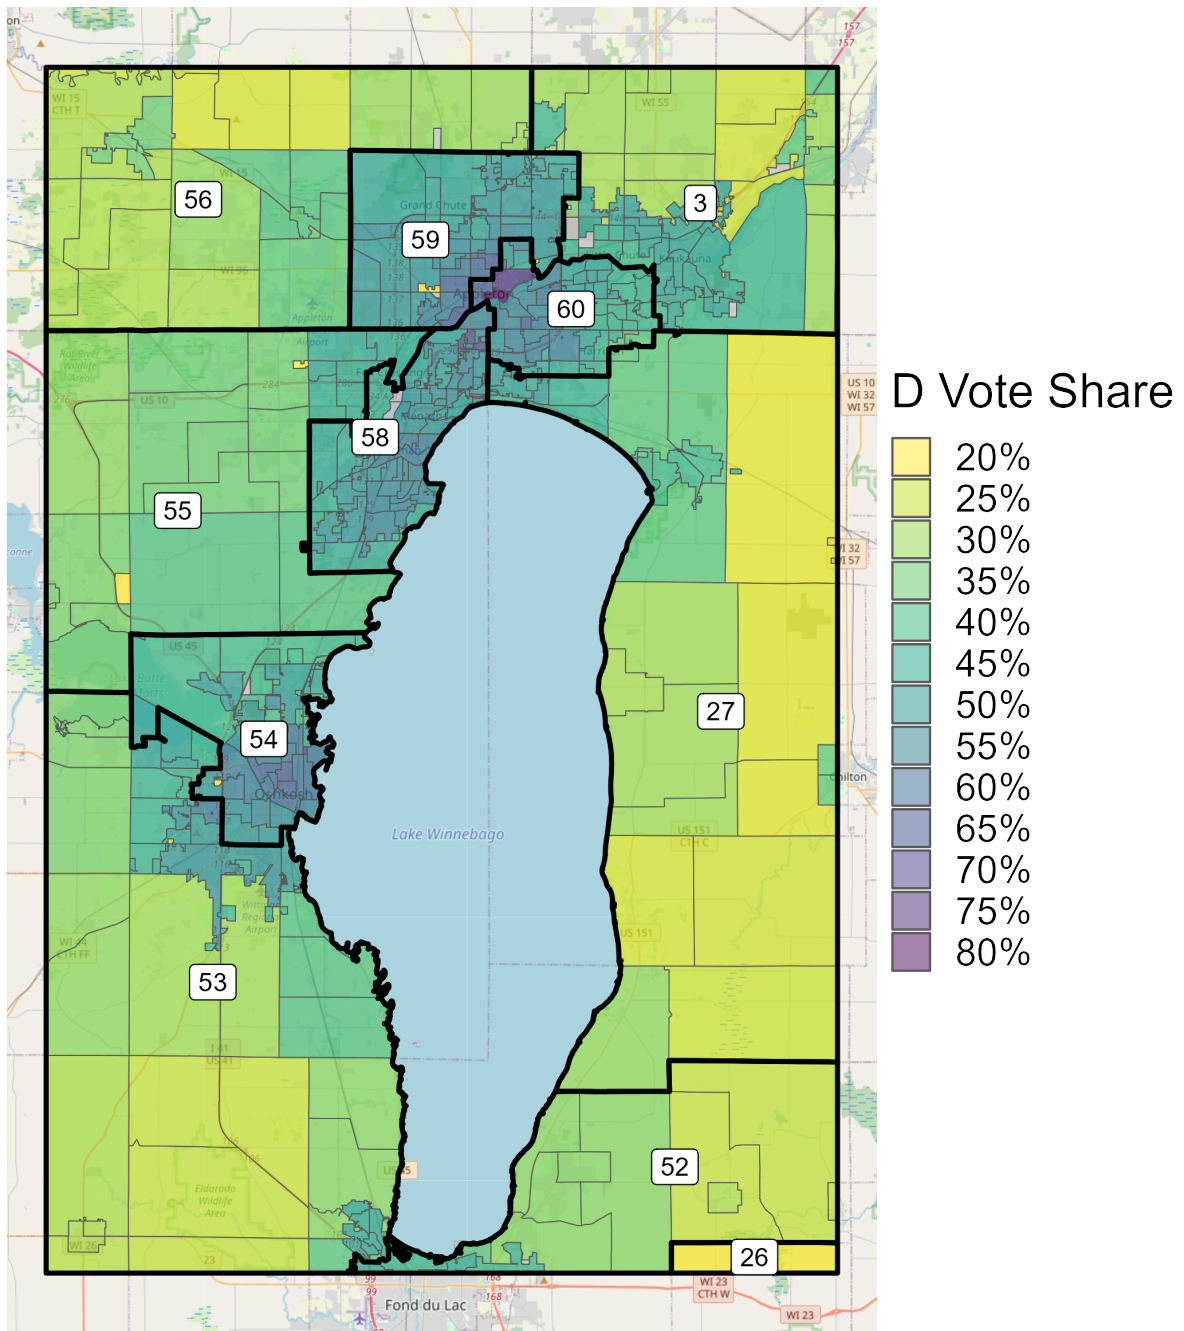

Again, we can see how certain changes are made that might only be suggested for partisan purposes. While most of the submitted maps create an additional Democratic or Democratic-leaning district around Eau Claire, the Wright map splits the city three ways, creating three Democratic-leaning districts.

Figure 40: Wright Assembly Map, Eau Claire Area

Likewise, most maps create a new Democratic-leaning district between Oshkosh and Appleton by creating a new district running north-south along the shores of Lake Winnebago. The Wright and Clarke maps, on the other hand, go one further by splitting Appleton three ways to try to squeeze in an additional Democratic-leaning district (both are similar in their approach; only the Wright map is shown below).

Figure 41: Wright Assembly Map, Lake Winnebago Area

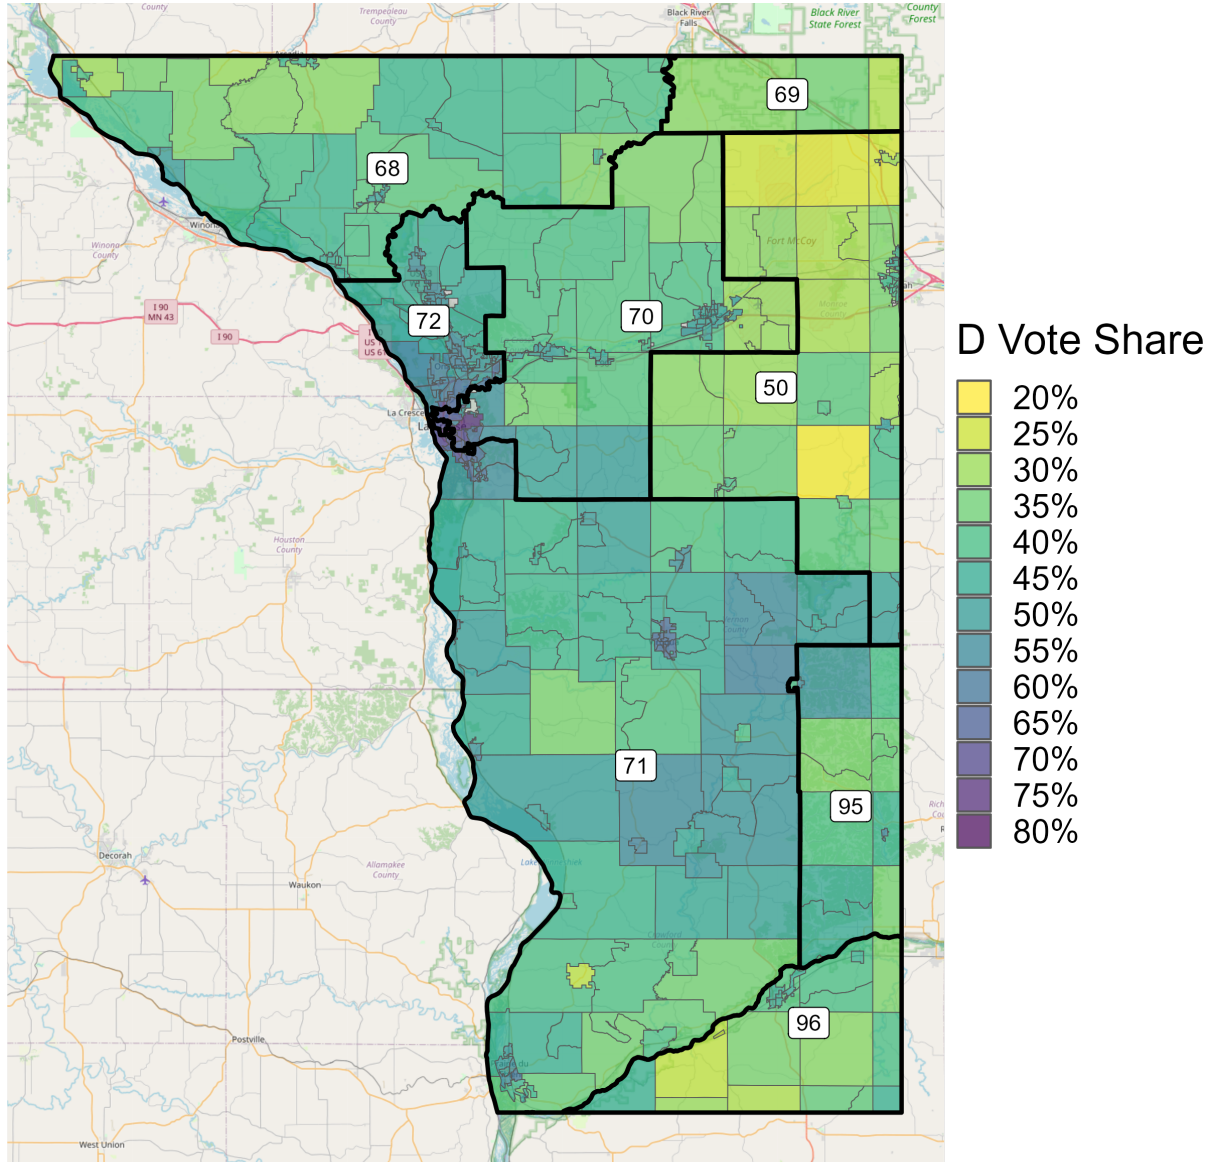

© OpenStreetMap contributors

While the City of Lacrosse remains intact in the Legislature’s map, most of the alternate maps create an additional Democratic district by splitting it. The Wright map, on the other hand, splits it three ways, in an attempt to create three Democratic districts

in the region.

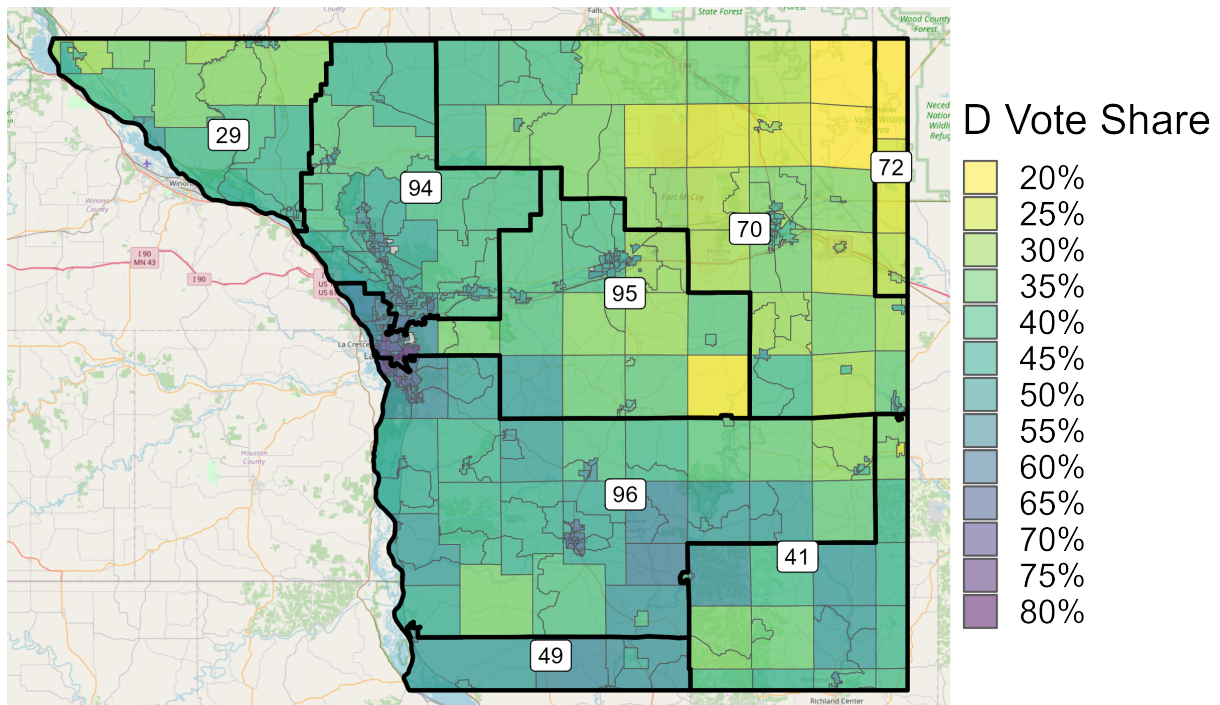

Figure 42: Wright Assembly Map, LaCrosse Area

© OpenStreetMap contributors

The governor’s map likewise splits the city three ways, extending districts out into the rural countryside to create (barely) three districts carried by President Biden.

Figure 43: Governor's Assembly Map, LaCrosse Area

© OpenStreetMap contributors

This leaves the two areas of greatest Democratic concentration: Madison and Milwaukee. In Madison, almost all of the submitted maps attempt to increase Democratic performance by employing a “pinwheel” concept (or, if one prefers, a “pizzamander”) by splitting the core of Dane County among multiple districts and then drawing wedge-like lines into the more heavily Republican exurbs and countryside. The Enacted Map creates 12 Democratic-leaning districts here. The Governor’s Map expands that to 16. While some of this would fall within the natural variance of the map, moves such as splitting Janesville – which can almost support an entire district on its own – in half are harder to justify as neutral moves. District 46 pairs Cottage Grove with Republican-leaning areas in suburban and rural areas of Dane and Jefferson counties, while District 42 mimics the heavily Democratic “arm” into Madison discussed above for the Senate map.

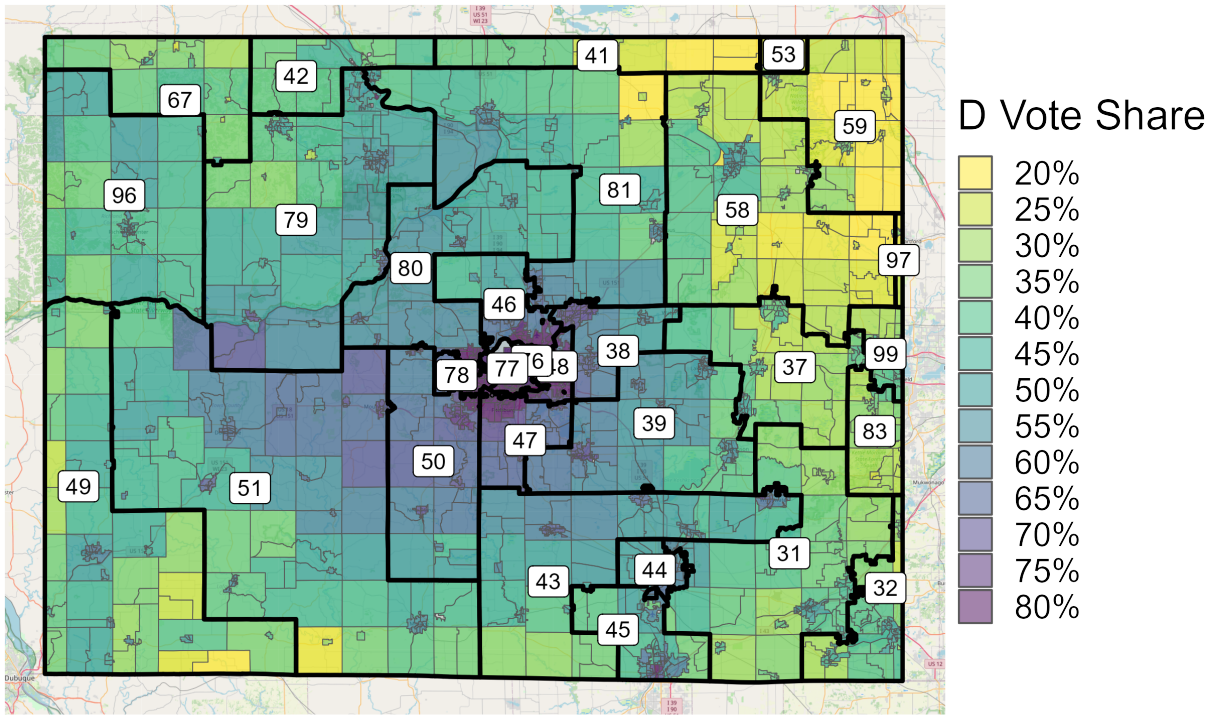

Figure 44: Governor’s Assembly Map, Madison Area

© OpenStreetMap contributors

Senate Democrats likewise create 16 districts, using the same technique of pairing Madison and its inner suburbs with rural areas further out from the core. This time, however, they split Janesville three ways. District 43 wraps around the area, joining a heavily Democratic city in Jefferson and Walworth counties (Whitewater) with more Republican areas to the west of Janesville.

Figure 45: Senate Democrats' Assembly Map, Madison Area

© OpenStreetMap contributors

The Clarke Map increases that number to 17. It heavily relies upon the “pinwheel” technique, in a series of districts that start with District 80 and move counterclockwise around Madison to District 44. It too splits Janesville in half, but also splits Sun Prairie in half to push District 39 to lean Democratic. District 37 also snakes its way out of Dane County to soak up heavily Republican areas near the Jefferson County/Waukesha County border.

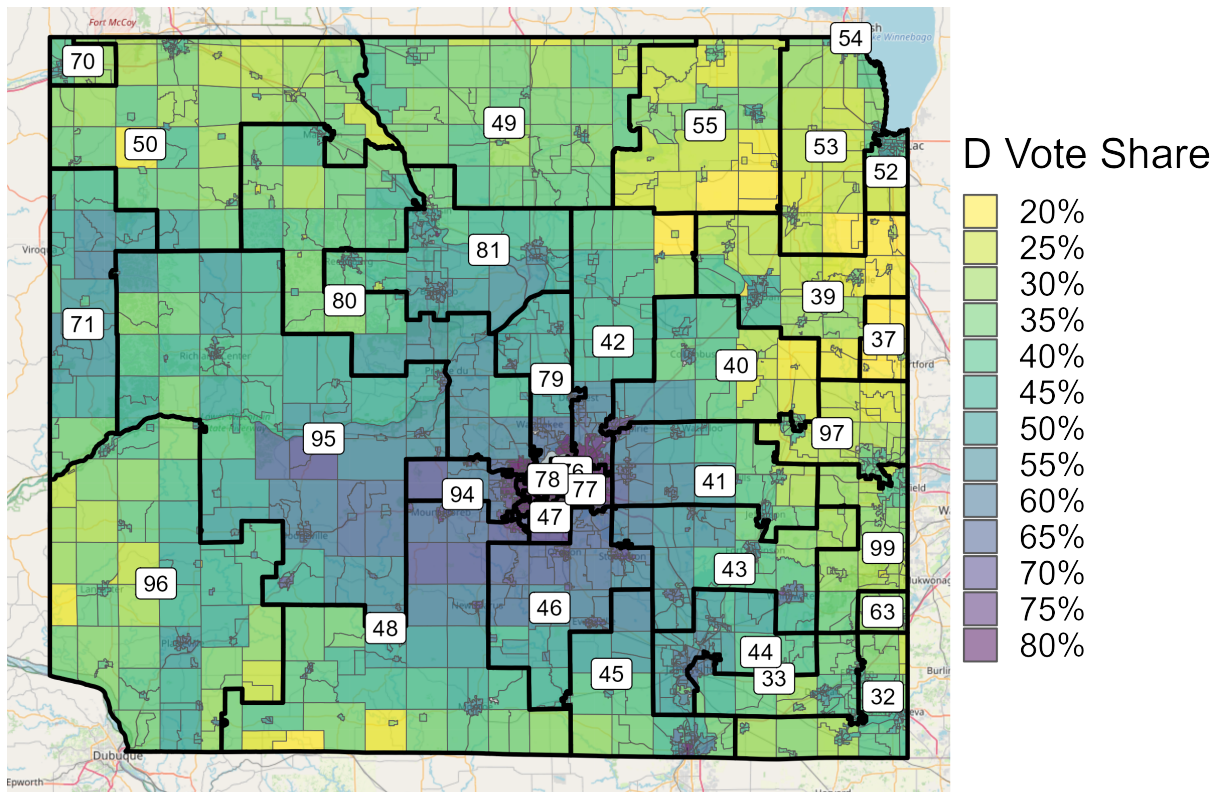

Figure 46: Clarke Assembly Map, Madison Area

© OpenStreetMap contributors

The Wright Map increases the number of Democratic districts to 18. Witness in particular District 80, which slithers from Middleton past the Wisconsin Dells to Juneau County. Or District 40, which takes the City of Juneau and extends the district it contains almost to the Iowa state line (this is an excellent example of how relying upon statewide compactness methods can conceal grotesque individual districts). The City of Sun Prairie is split in half, forming the Northern Tier of a series of stacked districts descending to the east of Madison, all of which achieve marginal Democratic status by taking heavily Democratic areas of the core of Dane County and extending them into the exurban and rural areas between Madison and Milwaukee. In the process, Jefferson County (which doesn't have sufficient population to support two districts) is split five ways. Walworth County, which also does not have sufficient population to support two districts, is split among six (it voted for Trump by 20 points).

Figure 47: Clarke Assembly Map, Madison Area

© OpenStreetMap contributors

The maps make various other adjustments that gain seats for Democrats here and there. Most of these pay at least some fealty to natural political boundaries. For example, all of the maps add a Democratic-leaning seat by the way that they split the City of Green Bay. But Green Bay has to be split. They all split Racine in half, adding an additional Democratic district based in that area. With that said, the only truly questionable split remaining is the design of Districts 20 and 63 in Milwaukee counties. The Senate Democrats and the Wright Map maintain the east-west division of those precincts, which creates two compact districts. Both the Governor's Map and the Clarke Map opt for a north-south split, extending the district containing Republican-leaning Oak Creek well into the city boundaries, past the airport. This creates an extra Democratic-leaning district, but does so at the expense of compactness.

4.4 Gerrymandering Index

I've summarized the data for the Assembly Maps in the gerrymandering indices below.

From left-to-right, the Johnson Map falls within the range of the ensembles, although it is out on a tail. The Legislature's map is next, falling just beyond the gerrymandering index for an ensemble plan. The remaining four maps, however, are pushed much further out, with (in order) the Senate Democrats' map, the Governor's Map, the Wright Map, and the Clarke map all appearing as substantial outliers sitting multiple standard deviations from the mean.

Figure 48: Gerrymandering indices of ensemble, versus proposed State Senate maps. Blue dashed line = Johnson Map; Black dashed line = Legislature's Map; Solid red line = Senate Dems' Map; Solid blue line = Governor's Map; Red dashed line = Wright Map; Black dotted line = Clarke Map

5 What is a fair map?

5.1 How do you properly measure partisanship?

When the efficiency gap was first proposed, it was intended as a retrospective metric. That is, after elections had been held on a map, one could look at the races that were held, and evaluate efficiency on the basis of who had won actual seats. *See* Nicholas O. Stephanopoulos and Eric. M. McGhee, *Partisan Gerrymandering and the Efficiency Gap*, 82 U. of Chi. L. Rev. 831 (2015). This presented problems, however, as the metric was especially sensitive to outcomes at the 50%-50% margin. If a Democrat received 50,001 out of 100,000 votes, that district would waste a single Democratic vote. But if the Democrat received 49,999 votes, the district would waste 99,999 votes. Given the inherent noise involved with actual elections, this posed problems for the stability of the efficiency gap. It also raised other issues, such as how uncontested elections should be dealt with.

This cycle, analysts have been more interested in utilizing a prospective efficiency gap. That is, the fairness of a map is evaluated before actual elections are held under the lines. Instead, elections from previous cycles, typically on a statewide basis, are used to evaluate the partisanship of a district. Some analysts examine individual races, while others utilize composites (that is, combinations of various races). This avoids the noise in evaluating an efficiency gap, and also eliminates concerns over imputation of uncontested elections.

However, it raises a different set of thorny questions. First and foremost among these is: “Which elections should we use to evaluate the map?” There are often multiple races available for evaluation, and which race(s) are selected can have a significant impact on the evaluation of the plan.

This issue became visible when Dr. Kenneth Mayer submitted his corrected expert report on Jan. 16, 2024. In this report, he seems to have eliminated two elections from his composite, resulting in a shift in some of his partisan fairness metrics (the reasons for this shift are obscure). We can see this by comparing Table 6 from his initial report with Table 6 from his corrected report.

Figure 49: Mayer Table 6, Initial and Corrected Reports

Table 6 - Summary of Measures of Partisan Neutrality										
	Dem Seats at 50-50 vote	Dem Seats at Baseline (50.5%)	Dem Vote Share to Obtain Majority	Comp. Seats	Seats Bias	Votes Bias	Global Symmetry	Efficiency Gap	Mean-Median	Declination
Assembly	45	47	52.2%	20	4.6%	2.2%	4.6%	4.5%	3.0%	10.3°
Senate	16	17	51.2%	10	3.3%	1.2%	2.7%	2.7%	0.9%	6.6°

Table 6 - Summary of Measures of Partisan Neutrality										
	Dem Seats at 50-50 vote	Dem Seats at Baseline (51.2%)	Dem Vote Share to Obtain Majority	Comp. Seats	Seats Bias	Votes Bias	Global Symmetry	Efficiency Gap	Mean-Median	Declination
Assembly	45	47	52.0%	16	4.1%	2.0%	3.2%	4.0%	2.3%	10.2°
Senate	16	18	50.6%	9	1.8%	0.6%	2.6%	0.8%	-0.52%	4.5°

This shift is difficult to object to since there is, to my knowledge, no agreed upon scientifically justified method for selecting races to place in an index. This raises the question: What would happen with other selections of races? I have data for 13 statewide races in Wisconsin: 2016 and 2020 presidential; 2016, 2018, and 2022 senatorial; 2018 and 2022 gubernatorial, secretary of state, attorney general and treasurer. This yields 8,191 combinations of races that could be selected.

I've evaluated the Governor's map under all of these combinations. As it turns out, the elections selected are very important in determining how the partisanship of the underlying map appears. Note that I did not evaluate the Seats Bias or Votes Bias, since those are simply restatements of other metrics.

As you can see, depending on the metric selected, the map is either a heavy Republican gerrymander or has a modest Democratic lean. It produces between 13 and

18 Democratic seats. Reverting those seats to a 50%-50% mean yields between 14 and 17 Democratic seats. Democrats would have to win between 46.8% of the vote and 54.3% of the vote. It would create between 5 and 18 competitive seats. The efficiency gap would range from -.142 (an extreme Republican gerrymander under every attempt to interpret the efficiency of which I am aware) to 0.019 (a modest pro-Democratic lean). The mean-median gap ranges between -0.038 and 0.008 (no one, to my knowledge, has attempted to set a threshold for a gerrymander under this metric). The declination ranges from between -0.205 to 0.047.

We could also exclude the less likely options, and focus only on the central 95% of race selections. In reality, justifying this would be difficult to do, since there are combinations that are probably more likely to be selected (such as 2020 presidential) that might land on a tail and that we would want to remain in consideration. Regardless, even restricting ourselves to the central 95% yields a wide range of possible outcomes.

Figure 50: Range of Outcomes, Partisan Fairness Metrics, Varying By Races Selected to Measure Partisanship (Governor's Map)

Metric	Minimum Value	Lower 95%	Upper 95%	Maximum Value
D Seats	13	15	17	18
D Seats @ 50%	14	15	15	17
D % Needed for Majority	46.8%	49.5%	52.9%	54.3%
Competitive Seats	5	7	13	18
Efficiency Gap	-0.142	-0.097	-0.028	0.019
Mean-Median	-0.038	-0.032	-0.003	0.008
Declination	-0.205	-0.166	-0.035	0.047

This is because, in the real world, candidates do matter. Perhaps less so than in

the past, but the political coalition put together by one candidate will not necessarily resemble the political coalition of another candidate. It is even more difficult to know how districts will perform without knowing which statewide candidate they are most likely to resemble. The endeavor is fraught. Note that this is less important for the simulation approach to redistricting, since a map drawn without respect to politics definitionally should resemble a politics-neutral ensemble regardless of which race is used to evaluate partisanship.

5.2 How important is competition?

Many of the reports filed in support of maps trumpet the number of competitive districts produced. Left unanswered is the question: How important are competitive districts?

This may seem like a spurious question. But there is actually a cottage industry in the political science devoted to the question of whether competitive districts actually improve representation. *E.g.*, Thomas Brunell, *Redistricting and Representation: Why Competitive Elections are Bad for America* (2008); Justin Buchler, "Competition, Representation, and Redistricting: The Case Against Competitive Congressional Districts," 17 *Jrnl. Theoretical Pol.* 431 (2005).

But this Court need not wade into that philosophical thicket. The practical problem with competitive districts is that making them a goal can make maps hyper-responsive. To see what I mean, imagine that the Assembly map were drawn such that every seat went for Joe Biden by a little less than a point, matching his statewide vote total. In a neutral year, Republicans might flip some of those seats, but Democrats would be well-positioned to win a strong majority. Now, imagine a year like 2018. Say that Democrats won 54% of the vote statewide. That would likely translate to them coming close to sweeping all of the seats in the chamber. On the other hand, in a year like 2022 where Republicans won the statewide vote by 8 points, Republicans would be in a strong

position to win almost all of seats in the legislature.¹

To see what I mean by this, examine the following table. Let us leverage Dr. DeFord’s analysis suggesting that President Biden’s vote share is reflective of state legislative outcomes in Wisconsin. Since the 2020 presidential election in Wisconsin was close to 50-50, assuming DeFord’s analysis is true, it would approximate a 50-50 Assembly election outcome. We can then take Joe Biden’s vote share in the seats in the Governor’s map and nudge the results sequentially by a half point toward Republicans (1% net), and then a half point toward Democrats.

Figure 51: Range of Outcomes, Partisan Fairness Metrics, Varying By Races Selected to Measure Partisanship (Governor’s Map)

R+10%	R+9%	R+8%	R+7%	R+6%	R+5%	R+4%	R+3%	R+2%	R+1%	0	D+1%	D+2%	D+3%	D+4%	D+5%	D+6%	D+7%	D+8%	D+9%	D+10%
33	36	41	42	43	43	45	46	46	47	49	51	52	52	52	53	53	53	53	54	54

As you can see, as things move toward Democrats, their position in the Assembly only gradually improves. But as things move toward Republicans, Democrats quickly fall off of a cliff. A year like 2022, where Republicans were winning the popular vote by near double-digits, could result in supermajorities in the legislature. Why this degree of hyper-responsiveness would be at all desirable is left unanswered. A similar analysis in the Senate is complicated by the fact that Senate seats are spread out over two cycles but regardless, we would see similar results. Republicans winning the statewide popular vote by eight points would place Democrats in a worse position than they are today; they would win only ten seats. An 8-point win in the other direction, however, yields only 18 Democratic seats.

¹Republicans’ margin was probably larger; they had more uncontested seats, which result in neither party being awarded any votes. See https://www.nytimes.com/interactive/2022/11/08/us/elections/results-wisconsin.html?action=click&pgtype=Article&state=default&module=election-results&context=election_recirc®ion=StateNavMenu. Since most of these seats have heavy partisan leans, including actual elections here would probably tilt the vote total further toward Republicans.

5.3 How should we define a fair map?

This also raises a related question: Which metric, if any, should be employed? Partisan fairness metrics are relatively new, are still evolving, and have a history of overpromising what they can deliver to courts. When the efficiency gap was first proposed, for example, it suggested “[u]nder circumstances that are very common in U.S. elections, it is unnecessary to sum the wasted votes in each individual district—a process that can be somewhat cumbersome. Instead, if we assume that all districts are equal in population (which is constitutionally required), and that there are only two parties (which is typical in single-member district systems), then the computation reduces through simple algebra to something quite straightforward $\text{Efficiency Gap} = \text{Seat Margin} - (2 \times \text{Vote Margin})$.” Stephanopoulos and McGhee, at 17. Of course, it was never quite that simple, since uncontested seats had to be imputed, a complex endeavor whose outcomes can depend on the technique employed.

More importantly, the algebra was *not* straightforward. It was later discovered that the proof of this equivalence only held true when turnout was equivalent across *districts*, which of course is almost never the case. Eric McGhee, “Measuring Efficiency in Redistricting”, 16 *Election L.J.* 417 (2017). Some have attempted to “save” the simpler format as a “turnout-adjusted” efficiency gap; regardless of one’s view of the merits of this, the existence of two sometimes-competing versions of the efficiency gap is not encouraging.

Even more distressing, the efficiency gap was represented as being closely related to partisan symmetry and creating symmetry with an efficiency gap of zero. See Complaint, *Gill v. Whitford*, Case No. 15-CV-421-bbc, available at https://vhdshf2oms2wcnsvk7sdv3so.blob.core.windows.net/thearp-media/documents/Complaint_7.8.15.pdf. However, as has recently been demonstrated (after the attempt to utilize the metric as part of a federal constitutional standard failed), this assertion was also false. See Jonathan Katz, Gary King, and Elizabeth Rosenblatt, 12 *American Political Science Rev.* 114 (2020) (“Stephanopoulos and McGhee (2015) introduce the efficiency gap and

claim it is “a new measure of partisan [a] symmetry” (quote repeated on pages 831, 834, 838, 849, and 899). We prove that this claim is false, and also convey the intuition and productive uses of the measure.”) (“The article then claims that partisan symmetry is satisfied when these wasted votes are equally divided between the parties. We show this claim is incorrect.”) (“The claim that “a party can win more than half the seats with half the votes only by exacerbating the efficiency gap in its favor” (p. 856) is also untrue.”).

Even beyond these problems, the fragility of the efficiency gap led to a need to add an additional layer of complex analysis. Some have tried “perturbing” vote shares – that is assuming a uniform swing in election results and exploring the potential outcomes as vote shares are moved in various directions. This adds the assumption that districts swing evenly across elections (that is, all move 2% toward Republicans or 3% toward Democrats at the same time). While this may be a decent approximation, it is only an approximation.

PlanScore is another attempt to rectify this problem, by using Bayesian Hierarchical Modeling to predict election outcomes in districts on the basis of the 2012 and 2016 presidential elections (but see *supra* Part III.a). It then samples outcomes from the posterior output to simulate a variety of electoral outcomes, and calculate the various efficiency gaps that are created. PlanScore is still relatively new, and will probably need multiple “real world” runs to have confidence in it.

I prefer simulations to partisan fairness metrics, given that it most precisely mimics the purpose of a single member district system of elections (see *infra* Part III.d) and can be used to detect when traditional principles are subverted to the pursuit of particular partisan outcomes. But even this approach can have issues. The initial method for simulating election outcomes proposed by Chen & Rodden appears not to sample uniformly from the distribution of available plans. This means that outcomes utilizing this technique may not actually yield samples of what a map drawn without respect to politics would yield. Fifeld et al., “The Essential Role of Empirical Validation in Legislative Redistricting Simulation,” 7 *Statistics and Public Policy* 52 (2020).

In other words, when seeking a fair map, the Court would have to choose among a variety of metrics, all of which are potentially sensitive to the choice of elections used to evaluate the metric, and most of which are relatively new and may later prove to be problematic.

Even beyond that, those metrics will raise important normative questions about what a fair map is. If a state has a “baseline” efficiency gap of -0.06, a gerrymander is defined at -0.075, and a party draws a map with an efficiency gap of -0.08, is that a gerrymander? Or should we account for the baseline level of distortion created by geography? If a competing party draws a map with an efficiency gap of -0.03, which is the fairer map: the one closer to zero, or the one closer to what a map drawn without any partisan intent would look like?

For that matter, if a competing party draws a map with an efficiency gap of 0.04, which is fairer? Drawing the latter map would put the state closer to a hypothetical zero efficiency gap (however we interpret that), but it would likely take quite a bit of reliance on political data to generate that outcome and would flip the benefitted party. The -0.08 map could probably be drawn accidentally without respect to political outcomes, but would cross the technical gerrymandering threshold. If there is only one way to draw a map with an efficiency gap of -0.04, and that is the friendliest map to Democrats possible in a state, must that map then be drawn? Is a neutral map one that is drawn with zero respect to politics? Or is it one drawn that zeroes out partisan imbalance (however defined).

All of these are defensible outcomes – at least from a non-legal point of view – depending upon the normative assumptions under which one operates. It’s just important to be aware that these types of choices are lurking under the seemingly straightforward surface of the partisan fairness ocean. It is also important to acknowledge that they tie in with legal concepts. A strong reliance on partisan fairness metrics standing alone would mean that the court is directing the Special Masters to remedy not only intentional gerrymandering, but also gerrymandering that occurs naturally. If not, a 0.00 mean-median

map is entirely irrelevant in a state with a substantial natural partisan skew. Moreover, emphasizing “partisan fairness neutrality”, instead of “natural geography neutrality”, reflects a choice to diminish, if not eliminate, any intent requirement from gerrymandering causes of action.

As a final note, Dr. DeFord asserts that there exists “[a] strong consensus in favor of the normative value of symmetry metrics among political scientists.” It is not at all clear what basis Dr. DeFord – who is not a political scientist – has for this assertion. I’m not aware of any public opinion polling among political scientists that might warrant such a conclusion, and the amount of effort directed toward developing redistricting simulations (including by Dr. DeFord) is at the very least indicative of a belief among some that a state’s underlying political geography is important. The various symmetry metrics certainly have their critics among political scientists and others. *See* Katz, King and Rosenblatt, *supra* (criticizing mean-median, efficiency gap, and lopsided margins metrics, among others); Christopher P. Chambers, et al., “Flaws in the Efficiency Gap,” 33 *Jrnl. of Law & Pol.* 1 (2017); Wendy K. Tam Cho, “Measuring Partisan Fairness: How Well Does the Efficiency gap Guard against Sophisticated as Well as Simple-Minded Modes of Partisan Discrimination,” 166 *U. of Penn. L.Rev. Online*, 17 (2017); Kristopher Tapp, “Measuring Political Gerrymandering,” (2018), *available at arXiv:1801.02541*; Barry Burden & Corwin Smidt, “Evaluating Legislative Districts Using Measures of Partisan Bias and Simulations,” 10 *Sage Open* (2020) (2020); Gregory S. Warrington, “A Comparison of Partisan-Gerrymandering Measures,” 18 *Elect. L.J.* 262 (2019).

Assuming such a consensus does exist, it is irrelevant here. While political scientists may have opinions as to how these various hypotheticals ought to play out, the truth is that political science expertise yields no specialized insight as to what the “proper” normative outcome is. Nor does the scope of that expertise include ultimate insight as to how fairness in a legal setting should be defined. Political science can explore the *implications* of various choices, but the ultimate choice is ultimately a question for courts or

for legislatures. I am unconvinced that there are particularly good answers to the questions posed a few paragraphs earlier, and could argue most of them either way. It is just important to acknowledge that situations like those described above will arise – indeed this litigation directly raises the question of what to do in a state where politics-neutral maps have Republican leans across a variety of operationalizations – and will have to be answered if partisan fairness is employed as a standard.

5.4 What is the role of partisanship in an single-member district system?

Finally, all of this raises the question of whether partisan fairness metrics even have a place in a system of district-based elections. After all there is a system of politics, employed throughout the world, that heightens the importance of partisanship: Proportional representation, or “PR.” The people of Wisconsin, for better or for worse, have opted for district-based representation. That would suggest intrinsically that there are other legitimate concerns than partisan fairness and may even suggest that partisan outcomes are not a concern of our electoral system (I should note that the simulations in the first report demonstrate that it is relatively straightforward to draw maps with far fewer county and location splits than any of the parties’ submitted maps create). As a learned scholar of elections once put it: “[T]he very reason for drawing geographic districts is to capture something unique about each particular place—to enable each distinct locality to have its voice heard (and its interests advanced) in the legislature. Under this conception of representation, concerns about statewide seats and votes are largely irrelevant. What matters, instead, is that each district make sense (because it corresponds to a territorial community), not that the consolidated votes in all the districts across the state bear some relationship to the seats controlled statewide by each party.” Nicholas Stephanopoulos, “Redistricting and the Territorial Community,” 160 *U. of Penn. L.Rev.* 1379, 1404 (2012).

CERTIFICATION REGARDING APPENDIX

I certify that the appendix meets the form requirements governing a respondent's appendix contained in Wis. Stat. §809.18(3)(b) and further certify that if the record is required by law to be confidential, the portions of the record included in the appendix are reproduced using one or more initials or other appropriate pseudonym or designation instead of full names of persons, specifically including juveniles and parents of juveniles, with a notation that the portions of the record have been so reproduced to preserve confidentiality and with appropriate references to the record.

Dated this 22nd day of January, 2024.

Respectfully submitted,

Electronically Signed by
Kevin M. St. John
